A test for second order stationarity of a multivariate time series

Carsten Jentsch* and Suhasini Subba Rao†

September 16, 2014

Abstract

It is well known that the discrete Fourier transforms (DFT) of a second order stationary time series between two distinct Fourier frequencies are asymptotically uncorrelated. In contrast for a large class of second order nonstationary time series, including locally stationary time series, this property does not hold. In this paper these starkly differing properties are used to define a global test for stationarity based on the DFT of a vector time series. It is shown that the test statistic under the null of stationarity asymptotically has a chi-squared distribution, whereas under the alternative of local stationarity asymptotically it has a noncentral chi-squared distribution. Further, if the time series is Gaussian and stationary, the test statistic is pivotal. However, in many econometric applications, the assumption of Gaussianity can be too strong, but under weaker conditions the test statistic involves an unknown variance that is extremely difficult to directly estimate from the data. To overcome this issue, a scheme to estimate the unknown variance, based on the stationary bootstrap, is proposed. The properties of the stationary bootstrap under both stationarity and nonstationarity are derived. These results are used to show consistency of the bootstrap estimator under stationarity and to derive the power of the test under nonstationarity. The method is illustrated with some simulations. The test is also used to test for stationarity of FTSE 100 and DAX 30 stock indexes from January 2011-December 2012.

Keywords and Phrases: Discrete Fourier transform; Local stationarity; Nonlinear time series; Stationary bootstrap; Testing for stationarity

1 Introduction

In several disciplines, as diverse as finance and the biological sciences, there has been a dramatic increase in the availability of multivariate time series data. In order to model this type of data, several multivariate time series models have been proposed, including the Vector Autoregressive model and the vector GARCH

*Department of Economics, University of Mannheim, L7, 3-5, 68131 Mannheim, Germany, cjentsch@mail.uni-mannheim.de
†Department of Statistics, Texas A&M University, College Station, Texas 77845, USA, suhasini@stat.tamu.edu (corresponding author)
model, to name but a few (see, for example, Lütkepohl (2005) and Laurent, Rombouts, and Violante (2012)). The majority of these models are constructed under the assumption that the underlying time series is stationary. For some time series this assumption can be too strong, especially over relatively long periods of time. However, relaxing this assumption, to allow for nonstationary time series models, can lead to complex models with a large number of parameters, which may not be straightforward to estimate. Therefore, before fitting a time series model, it is important to check whether or not the multivariate time series is second order stationary.

Over the years, various tests for second order stationarity for univariate time series have been proposed. These include, Priestley and Subba Rao (1969), Loretan and Phillips (1994), von Sachs and Neumann (1999), Paparoditis (2009, 2010), Dahlhaus and Polonik (2009), Dwivedi and Subba Rao (2011), Dette, Preuss, and Vetter (2011), Dahlhaus (2012), Example 10, Jentsch (2012), Lei, Wang, and Wang (2012) and Nason (2013). However, as far as we are aware there does not exist any tests for second order stationarity of multivariate time series (Jentsch (2012) does propose a test for multivariate stationarity, but the test was designed to detect the alternative of a multivariate periodically stationary time series). One crude solution is to individually test for stationarity for each of the univariate processes. However, there are a few drawbacks with this approach. The first is that most multiple testing schemes use a Bonferroni correction, which results in a test statistic which is extremely conservative. The second problem is that such a strategy can lead to misleading conclusions. For example if each of the marginal time series are second order stationary, but the cross-covariances are second order nonstationary, the above testing scheme would not be able detect the alternative. Therefore there is a need to develop a test for stationarity of a multivariate time series, which is the aim in this paper.

The majority of the univariate tests, are local, in the sense that they are based on comparing the local spectral densities over various segments. This approach suffers from some possible disadvantages. In particular, the spectral density may locally vary over time, but this does not imply that the process is second order nonstationary, for example Hidden Markov models can be stationary but the spectral density can vary according to the regime. For these reasons, we propose a global test for multivariate second order stationarity.

Our test is motivated by the tests for detecting periodic stationarity (see, for example, Goodman (1965), Hurd and Gerr (1991), Bloomfield, Hurd, and Lund (1994) and S. Olhede and Ombao (2013)) and the test for second order stationarity proposed in Dwivedi and Subba Rao (2011), all these tests use fundamental properties of the discrete Fourier transform (DFT). More precisely, the above mentioned periodic stationarity tests are based on the property that the discrete Fourier transform is correlated if the difference in the frequencies is a multiple of $2\pi/P$ (where $P$ denotes the periodicity), whereas Dwivedi and Subba Rao (2011) use the idea that the DFT asymptotically uncorrelates stationary time series, but
not nonstationary time series. Motivated by Dwivedi and Subba Rao (2011), in this paper, we exploit the uncorrelating property of the DFT to construct the test. However, the test proposed here differs from Dwivedi and Subba Rao (2011) in several important ways, these include (i) our test takes into account the multivariate nature of the time series, (ii) the test proposed here is defined such that it can detect a wider range of alternatives and (iii) the test in Dwivedi and Subba Rao (2011) assumes Gaussianity or linearity of the underlying time series (and calculates the power under the assumption of Gaussianity), which in several econometric applications is unrealistic, whereas our test allows for testing of nonlinear stationary time series.

In Section 2, we motivate the test statistic by comparing the covariance between the DFT of stationary and nonstationary time series, where we focus on the large class of nonstationary processes called locally stationary time series (see Dahlhaus (1997), Dahlhaus and Polonik (2006) and Dahlhaus (2012) for a review). Based on these observations, we define DFT covariances which in turn are used to define a Portmanteau-type test statistic. Under the assumption of Gaussianity, the test statistic is pivotal, however for non-Gaussian time series the test statistic involves a variance which is unknown and extremely difficult to estimate. If we were to ignore this variance (and thus implicitly assume Gaussianity) then the test can be unreliable. Therefore in Section 2.4 we propose a bootstrap procedure, based on the stationary bootstrap (first proposed in Politis and Romano (1994)), to estimate the variance. In Section 3, we derive the asymptotic sampling properties of the DFT covariance. We show that under the null hypothesis, the mean of the DFT covariance is asymptotically zero. In contrast, under the alternative of local stationarity, we show that the DFT covariance estimates nonstationary characteristics in the time series. These results are used to derive the sampling distribution of the test statistic. Since the stationary bootstrap is used to estimate the unknown variance, in Section 4, we analyze the stationary bootstrap when the underlying time series is stationary and nonstationary. Some of these results may be of independent interest. In Section 5 we show that under (fourth order) stationarity the bootstrap variance estimator is a consistent estimator of the true variance. In addition, we analyze the bootstrap variance estimator under nonstationarity and show that it has an influence on the power of the test. The test statistic involves some tuning parameters and in Section 6.1, we give some suggestions on how to select these tuning parameters. In Section 6.2, we analyze the performance of the test statistic under both the null and the alternative and compare the test statistic when the variance is estimated using the bootstrap and when Gaussianity is assumed. In the simulations we include both stationary GARCH and Markov switching models and for nonstationary models we consider time-varying linear models and the random walk. In Section 6.3, we apply our method to analyze the FTSE 100 and DAX 30 stock indexes. Typically, stationary GARCH-type models are used to model this type of data. However, even over the relatively short period January 2011-December 2012, the results from our test suggest that the log returns are nonstationary.
The proofs can be found in the Appendix.

2 The test statistic

2.1 Motivation

Let us suppose \( \{X_t = (X_{t,1}, \ldots, X_{t,d})', t \in \mathbb{Z}\} \) is a \( d \)-dimensional constant mean, multivariate time series and we observe \( \{X_t \}_{t=1}^T \). We define the vector discrete Fourier transform (DFT) as

\[
J_T(\omega_k) = \frac{1}{\sqrt{2\pi T}} \sum_{t=1}^T X_t e^{-it\omega_k}, \quad k = 1, \ldots, T,
\]

where \( \omega_k = \frac{2\pi k}{T} \) are the Fourier frequencies. Suppose that \( \{X_t\} \) is a second order stationary multivariate time series, where the autocovariance matrices of \( \{X_t\} \) satisfy

\[
\sum_{h=-\infty}^{\infty} |h| \cdot |\text{cov}(X_{h,j_1}, X_{0,j_2})| < \infty \quad \text{for all } j_1, j_2 = 1, \ldots, d.
\] (2.1)

It is well known for \( k_1 - k_2 \neq 0 \), that \( \text{cov}(J_{T,m}(\omega_{k_1}), J_{T,n}(\omega_{k_2})) = O\left(\frac{1}{T}\right) \) (uniformly in \( T, k_1 \), and \( k_2 \)), in other words the DFT has transformed a stationary time series into a sequence which is approximately uncorrelated. The behavior in the case that the vector time series is second order nonstationary is very different. To obtain an asymptotic expression for the covariance between the DFTs, we will use the rescaling device introduced by Dahlhaus (1997) to study locally stationary time series, which is a class of nonstationary processes. \( \{X_{t,T}\} \) is called a locally second order stationary time series, if its covariance structure changes slowly over time such that there exist smooth matrix functions \( \{\kappa(\cdot; r)\}_r \) which can approximate the time-varying covariance matrices. More precisely,

\[
|\text{cov}(X_{t,T}, X_{\tau,T}) - \kappa(t; \tau)|_1 \leq T^{-1}\kappa(t-\tau), \quad \text{where } \sum_{h} \kappa(h) < \infty.
\]

An example of a locally stationary model which satisfies these conditions is the time-varying moving average model defined in Dahlhaus (2012), equations (63)–(65) (with \( \ell(j) = \log(|j|)^{1+\epsilon}|j| \) for \( |j| \neq 0 \)). It is worth mentioning that Dahlhaus (2012) uses the slightly weaker condition \( \ell(j) = \log(|j|^{1+\epsilon}) \). In the Appendix (Lemma A.8), we show that

\[
\text{cov}(J_{T}(\omega_{k_1}), J_{T}(\omega_{k_2})) = \int_0^1 f(u; \omega_k) \exp(-i2\pi u(k_1 - k_2)) du + O\left(\frac{1}{T}\right),
\] (2.2)

uniformly in \( T, k_1 \) and \( k_2 \), where \( f(u; \omega) = \frac{1}{2\pi} \sum_{h=-\infty}^{\infty} \kappa(u; h) \exp(-ih\omega) \) is the local spectral density matrix (see Lemma A.8 for details). We recall if \( \{X_t\}_t \) is second order stationary then the ‘spectral density’ function \( f(u; \omega) \) does not depend on \( u \) and the above expression reduces to \( \text{cov}(J_{T}(\omega_{k_1}), J_{T}(\omega_{k_2})) = O\left(\frac{1}{T}\right) \) for \( k_1 - k_2 \neq 0 \). It is interesting to observe that for locally stationary time series its DFT sequence mimics the behavior of a time series, in the sense that the correlation between the DFTs decays the further apart the frequencies.
A further, related motivation for our test is that a time series \( \{X_t\} \) is second order stationary if and only if it admits the Fourier-Stieltjes integral (Cramér Representation)

\[
X_t = \int_0^{2\pi} \exp(it\omega) dZ(\omega),
\]  

(2.3)

where \( \{Z(\omega); \omega \in [0, 2\pi]\} \) is an orthogonal increment vector process (see for example, Yaglom (1987), Chapter 2). The DFT \( J_T(\omega_k) \) can be considered as an estimator of the increment \( dZ(\omega_k) \). The representation (2.3) can be generalized to include an increments process \( \{Z(\omega); \omega \in [0, 2\pi]\} \) which no longer has orthogonal increments. By doing so we induce second order nonstationarity within the time series, this general representation is called a Harmonizable time series (see for example, Yaglom (1987) and Lii and Rosenblatt (2002)). It is worth noting that periodically stationary time series have this representation as well as locally stationary time series, since we can represent \( \{X_{t,T}\} \) as

\[
X_{t,T} = \int_0^{2\pi} \exp(it\omega) dZ_T(\omega),
\]  

(2.4)

where \( Z_T(\omega) = \frac{1}{\sqrt{2\pi T}} \sum_{k=1}^{\left\lfloor \frac{T}{2\pi}\right\rfloor} J_T(\omega_k) \), noting that the correlation between the increments is given in (2.2). Therefore, testing for uncorrelatedness of the DFTs is effectively the same as testing for uncorrelatedness of the increment process.

### 2.2 The weighted DFT covariance

The discussion in the previous section suggests that to test for stationarity, we can transform the time series into the frequency domain and test if the vector sequence \( \{J_T(\omega_k)\} \) is asymptotically uncorrelated. Testing for uncorrelatedness of a multivariate time series is a well established technique in time series analysis (see, for example, Hosking (1980, 1981) and Escanciano and Lobato (2009)). Most of these tests are based on constructing a test statistic which is a function of sample autocovariance matrices of the time series. Motivated by these methods, we will define the weighted (standardized) covariance DFT and use this to define the test statistic.

To summarize the previous section, if \( \{X_t\} \) is a second order stationary time series which satisfies (2.1), then \( \text{E}(J_T(\omega_k)) = 0 \) (for \( k \neq 0, T/2, T \)) and \( \text{var}(J_T(\omega_k)) \to f(\omega_k) \) as \( T \to \infty \), where \( f: [0, 2\pi] \to \mathbb{C}^{d \times d} \) with

\[
f(\omega) = \{f_{j_1,j_2}(\omega); j_1, j_2 = 1, \ldots, d\} = \frac{1}{2\pi} \sum_{h=-\infty}^{\infty} \kappa(h) \exp(-ih\omega)
\]

is the spectral density matrix of \( \{X_t\} \), where \( \kappa(r) = \text{cov}(X_r, X_0) \). If the spectral density \( f(\omega) \) is nonsingular on \( [0, 2\pi] \), then its Cholesky decomposition is unique and well defined on \( [0, 2\pi] \). More precisely,

\[
f(\omega) = B(\omega)B(\omega)',
\]  

(2.5)
where $B(\omega)$ is a lower triangular matrix and $\overline{B(\omega)^\prime}$ denotes the transpose and complex conjugate of $B(\omega)$. Let $L(\omega_k) := B^{-1}(\omega_k)$, thus $L^{-1}(\omega_k) = \overline{L(\omega_k)^\prime}L(\omega_k)$. Therefore, if $\{X_t\}$ is a second order stationary time series, then the vector sequence, $\{L(\omega_1)J_T(\omega_1), \ldots, L(\omega_T)J_T(\omega_T)\}$, is asymptotically an uncorrelated sequence with a constant variance.

Of course, in reality the spectral density matrix $f(\omega)$ is unknown and has to be estimated from the data. Let $\hat{f}_T(\omega)$ be a nonparametric estimate of $f(\omega)$, where

$$
\hat{f}_T(\omega) = \frac{1}{2\pi T} \sum_{t,\tau=1}^{T} \lambda_0(t - \tau) \exp(-i(t - \tau) \omega)(X_t - \overline{X})(X_{\tau} - \overline{X})^\prime \quad \omega \in [0, 2\pi], \quad \omega \in [0, 2\pi],
$$

$\{\lambda_0(r) = \lambda(br)\}$ are the lag weights and $\overline{X} = \frac{1}{T} \sum_{t=1}^{T} X_t$. Below we state the assumptions we require on the lag window, which we use throughout this article.

**Assumption 2.1 (The lag window and bandwidth)** (K1) The lag window $\lambda : \mathbb{R} \rightarrow \mathbb{R}$, where $\lambda(\cdot)$ has a compact support $[1, 1]$, is symmetric about 0 with $\lambda(0) = 1$ such that the derivative $\lambda'(u)$ exists in $(0, 1)$ and is bounded. Some consequences of the above conditions are $\sum_h |\lambda_0(h)| = O(b^{-1})$, $\sum_h |h| \cdot |\lambda_0(h)| = O(b^{-2})$ and $|\lambda_0(h) - 1| \leq \sup_u |\lambda'(u)| \cdot |hb|$.

(K2) $T^{-1/2} << b << T^{-1/4}$.

Let $\hat{f}_T(\omega_k) = \overline{B(\omega_k)B(\omega_k)}$, where $\overline{B(\omega_k)}$ is the (lower-triangular) Cholesky decomposition of $\hat{f}_T(\omega_k)$ and $\hat{L}(\omega_k) := \overline{B^{-1}(\omega_k)}$. Thus $\overline{B(\omega_k)}$ and $\hat{L}(\omega_k)$ are estimators of $B(\omega_k)$ and $L(\omega_k)$ respectively.

Using the above spectral density matrix estimator, we now define the weighted DFT covariance matrix at lags $r$ and $\ell$

$$
\hat{C}_T(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} \hat{L}(\omega_k)J_T(\omega_k)J_T(\omega_{k+r}) \overline{L(\omega_{k+r})} \exp(i\ell \omega_k), \quad r > 0 \text{ and } \ell \in \mathbb{Z}. \quad (2.6)
$$

We observe that due to the periodicity of the DFT, $\hat{C}_T(r, \ell)$ is also periodic in $r$ with $\hat{C}_T(r, \ell) = \hat{C}_T(r+T, \ell)$ for all integers $r > 0$. To understand the motivation behind this definition, we recall that if the time series is second order stationary, then $L(\omega_k)J_T(\omega_k)$ is the DFT of a prewhitened multivariate time series. If the time series is nonstationary then $L(\omega_k)J_T(\omega_k)$ can be considered as the DFT of some linearly transformed multivariate time series. The correlations between $\{L(\omega_k)J_T(\omega_k); k\}$ are used to detect for nonstationarities in this transformed time series. However, if we restrict the DFT covariance to only $\{\hat{C}_T(r, 0); r\}$ then we will only be able to detect changes in the variance of the transformed time series. For the majority of nonstationary time series, the ‘nonstationarity’ can be detected here, but there can arise exceptional situations where changes can only be found in the higher order covariance lags and not the variance. By generalizing the covariance to $\hat{C}_T(r, \ell)$ the DFT covariance is able to detect changes in the transformed time series at covariance lag $\ell$. The precise details can be found in Section 3.3. It is worth mentioning
that there is a connection between \( \hat{C}_T(r, \ell) \) and classical frequency domain methods for stationary time series. For example, if we were to allow \( r = 0 \) we observe that in the univariate case \( \hat{C}_T(0,0) \) corresponds to the classical Whittle likelihood (where \( \hat{L}(\omega_k) \) is replaced with the square-root inverse of a spectral density function which has a parametric form, see for example, Whittle (1953), Walker (1963) and Eichler (2012)). Likewise, by removing \( \hat{L}(\omega_k) \) from the definition, we find that \( \hat{C}_T(0, \ell) \) corresponds to the sample Yule-Walker autocovariance of \( \{X_t\} \) at lag \( \ell \).

**Example 2.1** We illustrate the above for the univariate case \((d = 1)\). If the time series is second order stationary, then \( E|J_T(\omega)|^2 \to f(\omega) \), which means \( E|f(\omega)^{-1/2}J_T(\omega)|^2 \to 1 \). The corresponding weighted DFT covariance is

\[
\hat{C}_T(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} \frac{J_T(\omega_k)J_T(\omega_{k+r})}{f_T(\omega_k)^{1/2}f_T(\omega_{k+r})^{1/2}} \exp(i\ell\omega_k), \quad r > 0 \text{ and } \ell \in \mathbb{Z}.
\]

We will show later in this section that under Gaussianity, the asymptotic variance of \( \hat{C}_T(r, \ell) \) does not depend on any nuisance parameters. One can also define the DFT covariance without standardizing with \( f(\omega)^{-1/2} \). However, the variance of the non-standardized DFT covariance is a function of the spectral density function and only detects changes in the autocovariance function at lag \( \ell \).

In later sections, we derive the asymptotic distribution properties of \( \hat{C}_T(r, \ell) \). In particular, we show that under second order stationarity (and some additional technical conditions) and for all fixed \( m, n \in \mathbb{N} \), we have weak convergence

\[
\sqrt{T} \begin{pmatrix}
\Re \hat{K}_n(1) \\
\Im \hat{K}_n(1) \\
\vdots \\
\Re \hat{K}_n(m) \\
\Im \hat{K}_n(m)
\end{pmatrix} \xrightarrow{D} \mathcal{N} \left( \begin{pmatrix}
W_n & 0 & 0 & \ldots & 0 \\
0 & W_n & 0 & \ldots & 0 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & 0 & \ddots & W_n & 0 \\
0 & 0 & \ldots & 0 & W_n
\end{pmatrix} \right), \quad (2.7)
\]

as \( T \to \infty \), where \( \Re Z \) and \( \Im Z \) are the real and the imaginary parts of a random variable \( Z \), \( \mathbb{0}_d \) denotes the \( d \)-dimensional zero vector and

\[
\hat{K}_n(r) = \left( \text{vech}((\hat{C}_T(r,0))^\prime), \text{vech}((\hat{C}_T(r,1))^\prime), \ldots, \text{vech}((\hat{C}_T(r,n-1))^\prime) \right)^\prime 
\]

with \( \text{vech}(\hat{C}_T(r, \ell)) \) defined in (2.12) (see Theorem 3.3 for the details). This result is used to define the test statistic in Section 2.3. However, in order to construct the test statistic, we need to understand \( W_n \). Therefore, for the remainder of this section, we will discuss (2.7) and the form that \( W_n \) takes for various stationary time series (the remainder of this section can be skipped on first reading).
The DFT covariance of univariate stationary time series

We first consider the case that \( \{X_t\} \) is a univariate \((d = 1)\), fourth order stationary (to be precisely defined in Assumption 3.1) time series. To detect nonstationarity, we will consider the DFT covariance over various lags of \( \ell \) and define the vector

\[
\hat{K}_n(r) = \left( \hat{C}_T(r, 0), \ldots, \hat{C}_T(r, n-1) \right)'.
\]

Since \( \hat{K}_n(r) \) is a complex random vector we consider separately the real and imaginary parts denoted by \( \Re \hat{K}_n(r) \) and \( \Im \hat{K}_n(r) \), respectively. In the simple case that \( \{X_t\} \) is a univariate stationary Gaussian time series, it can be shown that the asymptotic normality result in (2.7) holds, where

\[
W_n = \frac{1}{2} \text{diag}(2, 1, 1, \ldots, 1).
\]

and \( \varnothing_d \) denotes the \( d \)-dimensional zero vector. Therefore, for stationary Gaussian time series, the distribution of \( \hat{K}_n(r) \) is asymptotically pivotal (does not depend on any unknown parameters). However, if we were to relax the assumption of Gaussianity, then a similar result holds but \( W_n \) is more complex, that is,

\[
W_n = \frac{1}{2} \text{diag}(2, 1, 1, \ldots, 1) + W_n^{(2)},
\]

where the \( (\ell_1 + 1, \ell_2 + 1) \)th element of \( W^{(2)} \) is \( W^{(2)}_{\ell_1+1, \ell_2+1} = \frac{1}{2} \kappa_{(\ell_1, \ell_2)} \) with

\[
\kappa_{(\ell_1, \ell_2)} = \frac{1}{2\pi} \int_0^{2\pi} \int_0^{2\pi} \frac{f_4(\lambda_1, -\lambda_1, -\lambda_2)}{f(\lambda_1)f(\lambda_2)} \exp(i\ell_1\lambda_1 - i\ell_2\lambda_2)d\lambda_1d\lambda_2
\]

and \( f_4 \) is the tri-spectral density \( f_4(\lambda_1, \lambda_2, \lambda_3) = \frac{1}{(2\pi)^3} \sum_{h_1, h_2, h_3 = -\infty}^{\infty} \kappa_4(h_1, h_2, h_3)\exp(-i(h_1\lambda_1 + h_2\lambda_2 + h_3\lambda_3)) \) and \( \kappa_4(t_1, t_2, t_3) = \text{cum}(X_{t_1}, X_{t_2}, X_{t_3}, X_0) \) (for statistical properties of the tri-spectral density see Brillinger (1981), Subba Rao and Gabr (1984) and Terdik (1999)). \( \kappa_{(\ell_1, \ell_2)} \) can be rewritten in terms of fourth order cumulants by observing that if we define the pre-whitened time series \( \{Z_t\} \) (where \( \{Z_t\} \) is a linear transformation of \( \{X_t\} \) which is uncorrelated) then

\[
\kappa_{(\ell_1, \ell_2)} = \sum_{h \in \mathbb{Z}} \text{cum}(Z_h, Z_{h+\ell_1}, Z_{h+\ell_2}, Z_0).
\]

The expression for \( W_n^{(2)} \) is unwieldy, but in certain situations (besides the Gaussian case) it has a simple form. For example, in the case that the time series \( \{X_t\} \) is non-Gaussian, but linear with transfer function \( A(\lambda) \), and innovations with variance \( \sigma^2 \) and fourth order cumulant \( \kappa_4 \), respectively, then the above reduces to

\[
\kappa_{(\ell_1, \ell_2)} = \frac{\kappa_4[A(\lambda_1)A(\lambda_2)]^2}{\sigma^4[A(\lambda_1)^2A(\lambda_2)]^2} \exp(i\ell_1\lambda_1 - i\ell_2\lambda_2)d\lambda_1d\lambda_2 = \frac{\kappa_4}{\sigma^4} \delta_{\ell_1, 0} \delta_{\ell_2, 0},
\]
where \( \delta_{jk} \) is the Kronecker delta. Therefore, for (univariate) linear time series, we have that the \((1,1)\)-entry of \( W_n^{(2)} \) equals \( \frac{2\pi}{\lambda} \) with all other entries being zero and \( W_n \) is still a diagonal matrix. This example illustrates that even in the univariate case the complexity of the variance of the DFT covariance \( \hat{K}_n(r) \) increases the more we relax the assumptions on the distribution. Regardless of the distribution of \( \{X_t\} \), so long as it satisfies (2.1) (and some mixing-type assumptions), then \( \hat{K}_n(r) \) is asymptotically normal and centered about zero.

The DFT covariance of multivariate stationary time series

We now consider the distribution of \( \hat{C}_T(r, \ell) \) in the multivariate case. We will show in Lemma A.11 (in the Appendix) that the covariance matrix of (vectorized) \( \hat{C}_T(r, 0) \) is singular. To avoid the singularity, we will only consider the lower triangular vectorized version of \( \hat{C}_T(r, \ell) \), i.e.

\[
\text{vech}(\hat{C}_T(r, \ell)) = (\hat{c}_{1,1}(r, \ell), \hat{c}_{2,1}(r, \ell), \ldots, \hat{c}_{d,1}(r, \ell), \hat{c}_{2,2}(r, \ell), \ldots, \hat{c}_{d,2}(r, \ell), \ldots, \hat{c}_{d,d}(r, \ell))^t,
\]

(2.12)

where \( \hat{c}_{j_1,j_2}(r, \ell) \) is the \((j_1,j_2)\)th element of \( \hat{C}_T(r, \ell) \), and we use this to define the \( nd(d+1)/2 \)-dimensional vector \( \hat{K}_n(r) \) (given in (2.8)). In the case that \( \{X_t\} \) is a Gaussian stationary time series we obtain a result analogous to (2.9) where similar to the univariate case \( W_n \) is a diagonal matrix with

\[
W_n^{(1)} = \begin{cases} \frac{1}{2} I_{d(d+1)/2} & \ell \neq 0 \\ \text{diag}(\lambda_1, \ldots, \lambda_{d(d+1)/2}) & \ell = 0 \end{cases}
\]

(2.13)

with

\[
\lambda_j = \begin{cases} 1, & j \in \{1 + \sum_{n=m+1} d n \text{ for } m \in \{1, 2, \ldots, d\} \} \\ \frac{1}{2}, & \text{otherwise} \end{cases}
\]

However, in the non-Gaussian case \( W_n \) is equal to the above diagonal matrix plus an additional (not necessarily diagonal) matrix consisting of the fourth order spectral densities, i.e. \( W_n \) consists of \( n^2 \) square blocks of dimension \( d(d+1)/2 \), where the \((\ell_1,1, \ell_2+1)\)th block is

\[
(W_n)_{\ell_1+1, \ell_2+1}^{(2)} = W_{\ell_1+1, \ell_2+1}^{(1)} \delta_{\ell_1, \ell_2} + W_{\ell_1+1, \ell_2+1}^{(2)}
\]

(2.14)

with \( W_{\ell_1, \ell_2}^{(1)} \) and \( W_{\ell_1, \ell_2}^{(2)} \) defined in (2.13) and in (2.17) below. In order to appreciate the structure of \( W_{\ell_1, \ell_2}^{(2)} \), we first consider some examples. We start by defining the multivariate version of (2.10)

\[
\kappa^{(j_1, j_2)}(j_1, j_2, j_3, j_4) = \frac{1}{2\pi} \int_0^{2\pi} \int_0^{2\pi} \sum_{s_1, s_2, s_3, s_4 = 1}^{d} L_{j_1 s_1}(\lambda_1) L_{j_2 s_2}(\lambda_1) L_{j_3 s_3}(\lambda_2) L_{j_4 s_4}(\lambda_2) \exp(i \ell_1 \lambda_1 - i \ell_2 \lambda_2) \times f_{s_1, s_2, s_3, s_4}(\lambda_1, -\lambda_1, -\lambda_2)d\lambda_1 d\lambda_2,
\]

(2.15)
where
\[
f_{4:s_1,s_2,s_3} (\lambda_1, \lambda_2, \lambda_3) = \frac{1}{(2\pi)^3} \sum_{h_1, h_2, h_3 = -\infty}^{\infty} \kappa_{4:s_1,s_2,s_3} (h_1, h_2, h_3) \exp(-i(h_1 \lambda_1 + h_2 \lambda_2 + h_3 \lambda_3))
\]
is the joint tri-spectral density of \( \{X_t\} \) and
\[
\kappa_{4:s_1,s_2,s_3} (h_1, h_2, h_3) = \text{cum}(X_{h_1,s_1}, X_{h_2,s_2}, X_{h_3,s_3}, X_{0,s_4}).
\]  
(2.16)

**Example 2.2 (Structure of \( W_n \))** For \( n \in \mathbb{N} \) and \( \ell_1, \ell_2 \in \{0, \ldots, n-1\} \), we have \( W_n^{(1)} \delta_{\ell_1, \ell_2} + W_n^{(2)} \), where:

(i) For \( d = 2 \), we have \( W_0^{(1)} = \frac{1}{2} \text{diag}(2, 1, 2) \) and for \( \ell \geq 1 \) \( W^{(1)} = \frac{1}{2} I_3 \).

\[
W_{\ell_1, \ell_2}^{(2)} = \frac{1}{2} \begin{pmatrix}
\kappa_{(\ell_1, \ell_2)}(1, 1, 1, 1) & \kappa_{(\ell_1, \ell_2)}(1, 1, 2, 1) & \kappa_{(\ell_1, \ell_2)}(1, 1, 2, 2) \\
\kappa_{(\ell_1, \ell_2)}(2, 1, 1, 1) & \kappa_{(\ell_1, \ell_2)}(2, 1, 2, 1) & \kappa_{(\ell_1, \ell_2)}(2, 1, 2, 2) \\
\kappa_{(\ell_1, \ell_2)}(2, 2, 1, 1) & \kappa_{(\ell_1, \ell_2)}(2, 2, 2, 1) & \kappa_{(\ell_1, \ell_2)}(2, 2, 2, 2)
\end{pmatrix}
\]

(ii) For \( d = 3 \), we have \( W_0^{(1)} = \frac{1}{2} \text{diag}(2, 1, 2, 1, 2) \), \( W_{\ell}^{(1)} = \frac{1}{2} I_6 \) for \( \ell \geq 1 \) and \( W_{\ell_1, \ell_2}^{(2)} \) is analogous to (i).

(iv) For general \( d \) and \( n = 1 \), we have \( W_n = W_0^{(1)} + W^{(2)} \), where \( W_0^{(1)} \) is the diagonal matrix defined in (2.13) and \( W^{(2)} = W_{0,0}^{(2)} \) (which is defined in (2.17), below).

We now define the general form of the block matrix \( W^{(2)} = (W_{\ell_1, \ell_2})_{\ell_1, \ell_2 = 0, \ldots, n-1} \), that is,
\[
W_{\ell_1, \ell_2}^{(2)} = E_d V_{\ell_1, \ell_2}^{(2)} E_d,
\]  
(2.17)

where \( E_d \) with \( E_d \text{vec}(A) = \text{vech}(A) \) is the \((d(d+1)/2 \times d^2)\) elimination matrix [cf. Lütkepohl (2006), p.662] that transforms the vec-version of a \((d \times d)\) matrix \( A \) to its vech-version. The entry \((j_1, j_2)\) of the \((d^2 \times d^2)\) matrix \( V_{\ell_1, \ell_2}^{(2)} \) is such that
\[
\left( V_{\ell_1, \ell_2}^{(2)} \right)_{j_1, j_2} = \kappa_{(\ell_1, \ell_2)} \left( (j_1 - 1) \mod d + 1, \left\lfloor \frac{j_1}{d} \right\rfloor, (j_2 - 1) \mod d + 1, \left\lfloor \frac{j_2}{d} \right\rfloor \right),
\]  
(2.18)

respectively, where \([x]\) is the smallest integer greater than or equal to \(x\).

**Example 2.3** (\( \kappa_{(\ell_1, \ell_2)}(j_1, j_2, j_3, j_4) \) under linearity of \( \{X_t\} \)) Suppose the additional assumption of linearity of the process \( \{X_t\} \) is satisfied, that is, \( \{X_t\} \) satisfies the representation
\[
X_t = \sum_{\nu = -\infty}^{\infty} \Gamma_{\nu} X_{t-\nu}, \quad t \in \mathbb{Z},
\]  
(2.19)
where \( \sum_{\nu=-\infty}^{\infty} |\Gamma_\nu|_1 \leq \infty, \Gamma_0 = \mathbf{I}_d \) and \( \{\epsilon_t, t \in \mathbb{Z}\} \) are zero mean, i.i.d. random vectors with \( \text{E}(\epsilon_t\epsilon'_t) = \Sigma_e \) positive definite and whose fourth moments exist. By plugging-in (2.19) in (2.16) and then evaluating the integrals in (2.15), the quantity \( k^{(\ell_1,\ell_2)}(j_1, j_2, j_3, j_4) \) becomes

\[
k^{(\ell_1,\ell_2)}(j_1, j_2, j_3, j_4) = \sum_{s_1, s_2, s_3, s_4 = 1}^{d} \kappa_{4:s_1, s_2, s_3, s_4} \left\{ \frac{1}{2\pi} \int_{0}^{2\pi} (\mathbf{L}(\lambda_1)\Gamma(\lambda_1))_{j_1s_1} \overline{(\mathbf{L}(\lambda_1)\Gamma(\lambda_1))_{j_2s_2}} \exp(i\ell_1\lambda_1)d\lambda_1 \right\}
\times \left\{ \frac{1}{2\pi} \int_{0}^{2\pi} (\mathbf{L}(\lambda_2)\Gamma(\lambda_2))_{j_3s_3} \overline{(\mathbf{L}(\lambda_2)\Gamma(\lambda_2))_{j_4s_4}} \exp(-i\ell_2\lambda_2)d\lambda_2 \right\},
\]

where \( \kappa_{4:s_1, s_2, s_3, s_4} = \text{cum}(e_{0,s_1}, e_{0,s_2}, e_{0,s_3}, e_{0,s_4}) \) and \( \Gamma(\omega) = \frac{1}{\sqrt{2\pi}} \sum_{\nu=-\infty}^{\infty} \Gamma_\nu e^{-i\nu\omega} \) is the transfer function of \( \{X_t\} \). The shape of \( k^{(\ell_1,\ell_2)}(j_1, j_2, j_3, j_4) \) is now discussed for two special cases of linearity.

(i) If \( \Gamma_\nu = 0 \) for \( \nu \neq 0 \), we have \( \mathbf{X} = \mathbf{e} \) and \( k^{(\ell_1,\ell_2)}(j_1, j_2, j_3, j_4) \) simplifies to

\[
k^{(\ell_1,\ell_2)}(j_1, j_2, j_3, j_4) = \tilde{\kappa}_{4:j_1, j_2, j_3, j_4} \delta_{\ell_1, 0} \delta_{\ell_2, 0},
\]

where \( \Sigma_e^{-1/2} \mathbf{e} = (\tilde{\epsilon}_{t,1}, \ldots, \tilde{\epsilon}_{t,d})' \) and \( \tilde{\kappa}_{4:s_1, s_2, s_3, s_4} = \text{cum}(\tilde{e}_{0,s_1}, \tilde{e}_{0,s_2}, \tilde{e}_{0,s_3}, \tilde{e}_{0,s_4}) \).

(ii) The univariate time series \( \{X_{t,k}\} \) are independent for \( k = 1, \ldots, d \) (the components of \( \{X_t\} \) are independent), then we have

\[
k^{(\ell_1,\ell_2)}(j_1, j_2, j_3, j_4) = \kappa_{4,j} \delta_{\ell_1,0} \delta_{\ell_2,0} \delta_{j_1 = j_2 = j_3 = j_4 = j},
\]

where \( \kappa_{4,j} = \text{cum}_4(e_{o,j})/\sigma_j^2 \) and \( \Sigma_e = \text{diag}(\sigma_1^2, \ldots, \sigma_d^2) \).

2.3 The test statistic

We now use the results in the previous section to motivate the test statistic. We have seen in (2.7) that \( \{\tilde{\mathbf{K}}_n(r)\} \) (and also \( \Re \tilde{\mathbf{K}}_n(r) \) and \( \Im \tilde{\mathbf{K}}_n(r) \)) are asymptotically uncorrelated. Therefore, we simply standardize \( \{\tilde{\mathbf{K}}_n(r)\} \) and define the test statistic

\[
T_{m,n,d} = \sqrt{\sum_{r=1}^{m} \left( |\mathbf{W}_n^{-1/2}\Re \tilde{\mathbf{K}}_n(r)|_2^2 + |\mathbf{W}_n^{-1/2}\Im \tilde{\mathbf{K}}_n(r)|_2^2 \right)},
\]

where \( \tilde{\mathbf{K}}_n(r) \) and \( \mathbf{W}_n \) are defined in (2.8) and (2.14), respectively, and \( |A|_2^2 = \text{tr}(A'A) \) denotes the squared Frobenius norm of a matrix \( A \). By using (2.7), it is clear that

\[
T_{m,n,d} \overset{D}{\rightarrow} \chi^2_{\text{mnd}(d+1)},
\]

where \( \chi^2_{\text{mnd}(d+1)} \) is a \( \chi^2 \)-distribution with \( \text{mnd}(d+1) \) degrees of freedom.

Therefore, using the above result, we reject the null of second order stationarity at the \( \alpha \times 100\% \) level if \( T_{m,n,d} > \chi^2_{\text{mnd}(d+1)}(1 - \alpha) \), where \( \chi^2_{\text{mnd}(d+1)}(1 - \alpha) \) is the \( (1 - \alpha) \)-quantile of the \( \chi^2 \)-distribution with \( \text{mnd}(d+1) \) degrees of freedom.
Example 2.4  

(i) In the univariate case \( (d = 1) \) using \( n = 1 \), the test statistic reduces to

\[
T_{m,1,1} = \sum_{r=1}^{m} \frac{|\hat{C}_T(r,0)|^2}{1 + \frac{1}{2} \kappa(0,0)},
\]

where \( \kappa(0,0) \) is defined in (2.10).

(ii) In most situations, it is probably enough to use \( n = 1 \). In this case the test statistic reduces to

\[
T_{m,1,d} = T \sum_{r=1}^{m} \left( |W_1^{-1/2} \text{vech}(\Re \hat{C}_n(r,0))|^2_2 + |W_1^{-1/2} \text{vech}(\Im \hat{C}_n(r,0))|^2_2 \right).
\]

(iii) If we can assume that \( \{X_t\} \) is Gaussian, then \( T_{m,n,d} \) has the simple form

\[
T_{m,n,d,G} = T \sum_{r=1}^{m} \left( |(W_0^{(1)})^{-1/2} \text{vech}(\Re \hat{C}_T(r,0))|^2_2 + |(W_0^{(1)})^{-1/2} \text{vech}(\Im \hat{C}_T(r,0))|^2_2 \right) + 2T \sum_{r=1}^{m} \sum_{\ell=1}^{n-1} \left( |\text{vech}(\Re \hat{C}_T(r,\ell))|^2_2 + |\text{vech}(\Im \hat{C}_T(r,\ell))|^2_2 \right),
\]

(2.21)

where \( W_0^{(1)} \) is a diagonal matrix composed of ones and halves defined in (2.13).

The above test statistic was constructed as if the standardization matrix \( W_n \) were known. However, only in the case of Gaussianity this matrix will be known, for non-Gaussian time series we need to estimate it. In the following section, we propose a bootstrap method for estimating \( W_n \).

2.4 A bootstrap estimator of the variance \( W_n \)

The proposed test does not make any model assumptions on the underlying time series. This level of generality means that the test statistic involves unknown parameters which, in practice, can be extremely difficult to directly estimate. The objective of this section is to construct a consistent estimator of these unknown parameters. We propose an estimator of the asymptotic variance matrix \( W_n \) using a block bootstrap procedure. There exist several well known block bootstrap methods, (cf. Lahiri (2003) and Kreiss and Lahiri (2012) for a review), but the majority of these sampling schemes, are nonstationary when conditioned on the original time series. An exception is the stationary bootstrap, proposed in Politis and Romano (1994) (see also Parker, Paparoditis, and Politis (2006)), which is designed such that the bootstrap distribution is stationary. As we are testing for stationarity, we use the stationary bootstrap to estimate the variance.

The bootstrap testing scheme

Step 1. Given the \( d \)-variate observations \( X_1, \ldots, X_T \), evaluate \( \text{vech}(\Re \hat{C}_T(r,\ell)) \) and \( \text{vech}(\Im \hat{C}_T(r,\ell)) \) for \( r = 1, \ldots, m \) and \( \ell = 0, \ldots, n - 1 \).
Step 2. Define the blocks

\[ B_{I, L} = \{ \mathbf{Y}_i, \ldots, \mathbf{Y}_{i+L-1} \} , \]

where \( \mathbf{Y}_j = \mathbf{X}_{j \mod T} - \overline{\mathbf{X}} \) (hence there is wrapping on a torus if \( j > T \)) and \( \overline{\mathbf{X}} = \frac{1}{T} \sum_{t=1}^{T} \mathbf{X}_t \). We will suppose that the points on the time series \( \{ I_i \} \) and the block lengths \( \{ L_i \} \) are iid random variables, where \( P(I_i = s) = T^{-1} \) for \( 1 \leq s \leq T \) (discrete uniform distribution) and \( P(I_i = s) = p(1-p)^{s-1} \) for \( s \geq 1 \) (geometric distribution).

Step 3. We draw blocks \( \{ B_{I_i, L_i} \} \), until the total length of the blocks \( \{ B_{I_i, L_i} \} \) satisfies \( \sum_{i=1}^{r} L_i \geq T \) and we discard the last \( \sum_{i=1}^{r} L_i - T \) values to get a bootstrap sample \( \mathbf{X}_{1_1}^*, \ldots, \mathbf{X}_{1_T}^* \).

Step 4. Define the bootstrap spectral density estimator

\[ \hat{f}_T^*(\omega_k) = \frac{1}{T} \sum_{j=-\lfloor \frac{T}{2} \rfloor}^{\lfloor T/2 \rfloor} K_b(\omega_k - \omega_j) \overline{\mathcal{J}_T^r}^*(\omega_j) \overline{\mathcal{J}_T^r}^*(\omega_j) , \tag{2.22} \]

where \( K_b(\omega) = \sum_{r=-\infty}^{\infty} \lambda_b(r) \exp(-i r \omega) \) and \( \overline{\mathcal{J}_T^r}^*(\omega_k) = \frac{1}{\sqrt{2 \pi T}} \sum_{t=1}^{T} (\mathbf{X}_t^* - \overline{\mathbf{X}}^*) \exp(-i t \omega_k) \) is the (centered) bootstrap DFT. Further, denote by \( \hat{\mathbf{B}}^*(\omega) \) the lower-triangular Cholesky matrix of \( \hat{f}_T^*(\omega_k) \), by \( \hat{\mathbf{L}}^*(\omega) = (\hat{\mathbf{B}}^*(\omega))^{-1} \) its inverse and compute the bootstrap DFT covariances

\[ \hat{\mathbf{C}}_T^*(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} \hat{\mathbf{L}}^*(\omega_k) \overline{\mathbf{J}_T^r}^*(\omega_k) \overline{\mathbf{J}_T^\ell}^*(\omega_k) \exp(i \ell \omega_k) . \tag{2.23} \]

Step 5. Repeat Steps 1 - 4 \( N \) times (where \( N \) is large), to obtain \( \text{vech}(\Re \hat{\mathbf{C}}_T^*(r, \ell))^{(j)} \) and \( \text{vech}(\Im \hat{\mathbf{C}}_T^*(r, \ell))^{(j)} \), \( j = 1, \ldots, N \). For \( r = 1, \ldots, m \) and \( \ell_1, \ell_2 = 0, \ldots, n - 1 \), we compute the bootstrap covariance estimators of the real parts, that is,

\[ \left( \hat{\mathbf{W}}^*_m(r) \right)_{\ell_1+1, \ell_2+1} = T \left( \frac{1}{N} \sum_{j=1}^{N} \text{vech}(\Re \hat{\mathbf{C}}_T^*(r, \ell_1))^{(j)} \text{vech}(\Re \hat{\mathbf{C}}_T^*(r, \ell_2))^{(j)}' - \left( \frac{1}{N} \sum_{j=1}^{N} \text{vech}(\Re \hat{\mathbf{C}}_T^*(r, \ell_1))^{(j)} \right) \left( \frac{1}{N} \sum_{j=1}^{N} \text{vech}(\Re \hat{\mathbf{C}}_T^*(r, \ell_2))^{(j)} \right)' \right) \tag{2.24} \]

and, similarly, we define its analogues \( \left( \hat{\mathbf{W}}^*_3(r) \right)_{\ell_1+1, \ell_2+1} \) using the imaginary parts.

Step 6. Define the bootstrap covariance estimator \( \left( \hat{\mathbf{W}}^*_*(r) \right)_{\ell_1+1, \ell_2+1} \) as

\[ \left( \hat{\mathbf{W}}^*_*(r) \right)_{\ell_1+1, \ell_2+1} = \frac{1}{2} \left[ \left( \hat{\mathbf{W}}^*_m(r) \right)_{\ell_1+1, \ell_2+1} + \left( \hat{\mathbf{W}}^*_3(r) \right)_{\ell_1+1, \ell_2+1} \right] , \]

and let \( \hat{\mathbf{W}}^*_*(r) = \left( \left( \hat{\mathbf{W}}^*_*(r) \right)_{\ell_1+1, \ell_2+1} \right)_{\ell_1, \ell_2=0, \ldots, n-1} \) be the bootstrap estimator of the blocks of \( \mathbf{W}_{m,n} \) defined in (3.6) that correspond to \( \Re \hat{\mathbf{K}}_n(r) \) and \( \Im \hat{\mathbf{K}}_n(r) \).
Step 7. Finally, define the bootstrap test statistic $T^*_{m,n,d}$ as

$$T^*_{m,n,d} = T \sum_{r=1}^{m} \left( |(W^*(r))^{-1/2} \hat{\mathbf{K}}_{n}(r)|^2 \right)^{1/2} + |(\hat{W}^*(r))^{-1/2} \hat{\mathbf{K}}_{n}(r)|^2$$

and reject $H_0$ if $T^*_{m,n,d} > \chi^2_{mnd(d+1)}(1 - \alpha)$, where $\chi^2_{mnd(d+1)}(1 - \alpha)$ is the $(1 - \alpha)$-quantile of the $\chi^2$-distribution with $mnd(d + 1)$ degrees of freedom to obtain a test of asymptotic level $\alpha \in (0, 1)$.

**Remark 2.1 (Step 4)* A simple variant of the above bootstrap, is to use the spectral density estimator $\hat{f}_T(\omega)$ rather than bootstrap spectral density estimator $\hat{f}^*_T(\omega)$ i.e.

$$\hat{C}^*_T(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} \hat{L}(\omega_k) \hat{J}_T(\omega_k) \hat{J}_T(\omega_{k+r}) \overline{\hat{L}(\omega_{k+r})} \exp(i \ell \omega_k).$$

Using the above bootstrap covariance greatly simplifies the speed of the bootstrap procedure and the theoretical analysis of the bootstrap (in particular the assumptions required). However, empirical evidence suggests that estimating the spectral density matrix at each bootstrap sample gives a better finite sample approximation of the variance (though we cannot theoretically prove that using $\hat{C}^*_T(r, \ell)$ gives a better variance approximation than $\hat{C}_T^*(r, \ell)$).

We observe that because the blocks are random and their length is determined by a geometric distribution, their lengths vary. However, the mean length of a block is approximately $1/p$ (only approximately since only block lengths less than length $T$ are used in the scheme). As it has to be assumed that $p \to 0$ and $Tp \to \infty$ as $T \to \infty$, the mean block length increases as the sample size $T$ grows. However, we will show in Section 5 that a sufficient condition for consistency of the stationary bootstrap estimator is that $Tp^4 \to \infty$ as $T \to \infty$. This condition constrains the mean length of the block and prevents it growing too fast.

**Remark 2.2** An interesting variant on the above scheme is to use the bootstrap DFT covariances $\{\hat{C}^*_T(r, \ell)\}$ to directly construct bootstrap rejection regions for the test statistic. However, in this paper we will only use the $\chi^2$-approximation rather than the bootstrap distribution. It is worth noting that the moments of this bootstrap distribution can be evaluated using the results in Section 4.

### 3 Analysis of the DFT covariance under stationarity and nonstationarity of the time series

#### 3.1 The DFT covariance $\hat{C}_T(r, \ell)$ under stationarity

Directly deriving the sampling properties of $\hat{C}_T(r, \ell)$ is not possible as it involves the estimators $\hat{L}(\omega)$. Instead, in the analysis below, we replace $\hat{L}(\omega)$ by its deterministic limit $L(\omega)$, and consider the quantity

$$\tilde{C}_T(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} L(\omega_k) L_T(\omega_k) L_T(\omega_{k+r}) \overline{L(\omega_{k+r})} \exp(i \ell \omega_k).$$
Below, we show that \( \hat{C}_T(r, \ell) \) and \( \tilde{C}_T(r, \ell) \) are asymptotically equivalent. This allows us to analyze \( \tilde{C}_T(r, \ell) \) without any loss in generality. We will require the following assumptions.

3.1.1 Assumptions

Let \( | \cdot |_p \) denote the \( \ell_p \)-norm of a vector or matrix, i.e. \( |A|_p = (\sum_{i,j} |A_{ij}|^p)^{1/p} \) for some matrix \( A = (a_{ij}) \) and let \( \|X\|_p = (E|X|^p)^{1/p} \).

Assumption 3.1 (The process \( \{X_t\} \)) (P1) Let us suppose that \( \{X_t, t \in \mathbb{Z}\} \) is a \( d \)-variate constant mean, fourth order stationary (i.e. the first, second, third and fourth order moments of the time series are invariant to shift), \( \alpha \)-mixing time series which satisfies

\[
\sup_{k \in \mathbb{Z}} \sup_{A \in \sigma(X_{t+k}, X_{t+k+1}, \ldots)} \sup_{B \in \sigma(X_{t-1}, X_{t-2}, \ldots)} |P(A \cap B) - P(A)P(B)| \leq Ct^{-\alpha}, \quad t > 0, \tag{3.2}
\]

for constants \( C < \infty \) and \( \alpha > 0 \).

(P2) For some \( s > \frac{4\alpha}{\alpha-6} > 0 \) with \( \alpha \) such that (3.2) holds, we have \( \sup_{t \in \mathbb{Z}} \|X_t\|_s < \infty \).

(P3) The spectral density matrix \( f(\omega) \) is non-singular on \( [0, 2\pi] \).

(P4) For some \( s > \frac{8\alpha}{\alpha-7} > 0 \) with \( \alpha \) such that (3.2) holds, we have \( \sup_{t \in \mathbb{Z}} \|X_t\|_s < \infty \).

(P5) For a given lag order \( n \), let \( W_n \) be the variance matrix defined in (2.14), then \( W_n \) is assumed to be non-singular.

Some comments on the assumptions are in order. The \( \alpha \)-mixing assumption is satisfied by a wide range of processes, including, under certain assumptions on the innovations, the vector AR models (see Pham and Tran (1985)) and other Markov models which are irreducible (cf. Feigin and Tweedie (1985), Mokkadem (1990), Meyn and Tweedie (1993), Bousamma (1998), Franke, Stockis, and Tadjuidje-Kamgaing (2010)). We show in Corollary A.1 that Assumption (P2) implies \( \sum_{h=-\infty}^{\infty} |h| \cdot |\text{cov}(X_{h,j_1}, X_{0,j_2})| < \infty \) for all \( j_1, j_2 = 1, \ldots, d \) and absolute summability of the fourth order cumulants. In addition, Assumption (P2) is required to show asymptotic normality of \( \hat{C}_T(r, \ell) \) (using a Mixingale proof). Assumption (P4) is slightly stronger than (P2) and it is used to show the asymptotic equivalence of \( \sqrt{T}\hat{C}_T(r, \ell) \) and \( \sqrt{T}\tilde{C}_T(r, \ell) \). In the case that the multivariate time series \( \{X_t\} \) is geometric mixing, Assumption (P4) implies that for some \( \delta > 0 \), \( (8 + \delta) \)-moments of \( \{X_t\} \) should exist. Assumption (P5) is immediately satisfied in the case that \( \{X_t\} \) is a Gaussian time series. In this case \( W_n \) is a diagonal matrix (see (2.14)).

Remark 3.1 (The fourth order stationarity assumption) Although the purpose of this paper is to derive a test for second order stationarity, we derive the proposed test statistic under the assumption

15
of fourth order stationarity of \( \{ X_t \} \) (see Theorem 3.3). The main advantage of this slightly stronger assumption is that it guarantees that the DFT covariances \( \hat{C}_T(r_1, \ell) \) and \( \hat{C}_T(r_2, \ell) \) are asymptotically uncorrelated at different lags \( r_1 \neq r_2 \). For details see the end of the proof of Theorem 3.2, on the bounds of the fourth order cumulant term).

3.2 The sampling properties of \( \hat{C}_T(r, \ell) \) under the assumption of fourth order stationarity

Using the above assumptions we have the following result.

Theorem 3.1 (Asymptotic equivalence of \( \hat{C}_T(r, \ell) \) and \( \hat{C}_T(r, \ell) \) under the null) Suppose Assumption 3.1 is satisfied and let \( \hat{C}_T(r, \ell) \) and \( \hat{C}_T(r, \ell) \) be defined as in (2.6) and (3.1), respectively. Then we have

\[
\sqrt{T} | \hat{C}_T(r, \ell) - \hat{C}_T(r, \ell) |_1 = O_p \left( \frac{1}{b \sqrt{T}} + b + b^2 \sqrt{T} \right).
\]

We now obtain the mean and variance of \( \hat{C}_T(r, \ell) \) under the stated assumptions. Let \( \tilde{c}_{j_1,j_2}(r, \ell) = \hat{C}_T(r, \ell)_{j_1,j_2} \) denote entry \((j_1, j_2)\) of the unobserved \((d \times d)\) DFT covariance matrix \( \hat{C}_T(r, \ell) \).

Theorem 3.2 (First and second order structure of \( \{ \tilde{C}_T(r, \ell) \} \)) Suppose \( \sum_h |h| | \text{cov}(X_{h,1}, X_{0,2})| < \infty \) and \( \sum_h |h| | \text{cum}(X_{h,1}, X_{h,2}, X_{h,3,1}, X_{0,4})| < \infty \) hold for all \( j_1, \ldots, j_4 = 1, \ldots, d \) and \( i = 1, 2, 3 \) (satisfied by Assumption 3.1(P1,P2)). Then, the following assertions are true

(i) For all fixed \( r \in \mathbb{N} \) and \( \ell \in \mathbb{Z} \), we have \( E(\tilde{C}_T(r, \ell)) = O(\frac{1}{T}) \).

(ii) For fixed \( r_1, r_2 \in \mathbb{N} \) and \( \ell_1, \ell_2 \in \mathbb{Z} \) and all \( j_1, j_2, j_3, j_4 \in \{1, \ldots, d\} \), we have

\[
T \text{cov} \left( \Re \tilde{c}_{j_1,j_2}(r_1, \ell_1), \Re \tilde{c}_{j_3,j_4}(r_2, \ell_2) \right) = \frac{1}{2} \left\{ \delta_{j_1,j_3} \delta_{j_2,j_4} \delta_{\ell_1,\ell_2} + \delta_{j_1,j_4} \delta_{j_2,j_3} \delta_{\ell_1,-\ell_2} \right\} \delta_{r_1,r_2} + \frac{1}{2} K(\ell_1, \ell_2)(j_1, j_2, j_3, j_4) \delta_{r_1,r_2} + O \left( \frac{1}{T} \right),
\]

(3.3)

\[
T \text{cov} \left( \Re \tilde{c}_{j_1,j_2}(r_1, \ell_1), \Im \tilde{c}_{j_3,j_4}(r_2, \ell_2) \right) = O(\frac{1}{T}) \quad \text{and}
\]

\[
T \text{cov} \left( \Im \tilde{c}_{j_1,j_2}(r_1, \ell_1), \Re \tilde{c}_{j_3,j_4}(r_2, \ell_2) \right) = \frac{1}{2} \left\{ \delta_{j_1,j_3} \delta_{j_2,j_4} \delta_{\ell_1,\ell_2} + \delta_{j_1,j_4} \delta_{j_2,j_3} \delta_{\ell_1,-\ell_2} \right\} \delta_{r_1,r_2} + \frac{1}{2} K(\ell_1, \ell_2)(j_1, j_2, j_3, j_4) \delta_{r_1,r_2} + O \left( \frac{1}{T} \right),
\]

(3.4)

where \( \delta_{jk} = 1 \) if \( j = k \) and \( \delta_{jk} = 0 \) otherwise.

Below we state the asymptotic normality result, which forms the basis of the test statistic.
Theorem 3.3 (Asymptotic distribution of \(\text{vech}(\hat{C}_T(r, \ell))\) under the null) Suppose Assumptions 2.1 and 3.1 hold. Let the \(nd(d+1)/2\)-dimensional vector \(\hat{K}_n(r)\) be defined as in (2.8). Then, for fixed \(m, n \in \mathbb{N}\), we have

\[
\sqrt{T} \begin{pmatrix}
\Re \hat{K}_n(1) \\
\Im \hat{K}_n(1) \\
\vdots \\
\Re \hat{K}_n(m) \\
\Im \hat{K}_n(m)
\end{pmatrix} \xrightarrow{D} \mathcal{N}(0_{mnd(d+1)}, W_{m,n}),
\]

(3.5)

where \(W_{m,n}\) is a \((mnd(d + 1) \times mnd(d + 1))\) block diagonal matrix

\[
W_{m,n} = \text{diag}(\underbrace{W_n, \ldots, W_n}_{2m \text{ times}}),
\]

(3.6)

and \(W_n\) is defined in (2.17).

The above theorem immediately gives the asymptotic distribution of the test statistic.

Theorem 3.4 (Limiting distribution of \(T_{m,n,d}\) under the null) Suppose that Assumptions 2.1 and 3.1 are satisfied. Then we have

\[
T_{m,n,d} \xrightarrow{D} \chi^2_{mnd(d+1)},
\]

where \(\chi^2_{mnd(d+1)}\) is a \(\chi^2\)-distribution with \(mnd(d + 1)\) degrees of freedom.

3.3 Behavior of \(\hat{C}_T(r, \ell)\) for locally stationary time series

We now consider the behavior of the DFT covariance \(\hat{C}_T(r, \ell)\) when the underlying process is second order nonstationary. There are several different alternatives one can consider, including unit root processes, periodically stationary time series, time series with change points etc. However, here we shall focus on time series whose correlation structure changes slowly over time (early work on time-varying time series include Priestley (1965), Subba Rao (1970) and Hallin (1984)). As in nonparametric regression and other work on nonparametric statistics we use the rescaling device to develop the asymptotic theory. The same tool has been used, for example, in nonparametric time series by Robinson (1989) and by Dahlhaus (1997) in his definition of local stationarity. We use rescaling to define a locally stationary process as a time series whose second order structure can be ‘locally’ approximated by the covariance function of a stationary time series (see Dahlhaus (1997), Dahlhaus and Polonik (2006) and Dahlhaus (2012), for a recent overview of the current state-of-the-art).
3.3.1 Assumptions

In order to prove the results in this paper for the case of local stationarity, we require the following assumptions.

Assumption 3.2 (Locally stationary vector processes) Let us suppose that the locally stationary process \( \{X_{s,t}\} \) is a \( d \)-variate, constant mean time series that satisfies the following assumptions:

(L1) \( \{X_{s,t}\} \) is an \( \alpha \)-mixing time series which satisfies

\[
\sup_{k,T \in \mathbb{Z}} \sup_{A \in \sigma(\{X_{s+k,T} \downarrow_{s+k+1,T}\})} \sup_{B \in \sigma(\{X_{s+k,T} \downarrow_{s+k-1,T}\})} \left| P(A \cap B) - P(A)P(B) \right| \leq C t^{-\alpha}, \quad t > 0
\]

for constants \( C < \infty \) and \( \alpha > 0 \).

(L2) There exists a covariance function \( \{ \kappa(u; \omega) \}_{h} \) and function \( \kappa(h) \) such that \( \text{cov}(X_{1,T}, X_{2,T}) - \kappa(\frac{t_1 - t_2}{2}, t_1 - t_2) \)

\[
\frac{1}{h} \kappa(t_1 - t_2). \quad \text{We assume the functions} \quad \{ \kappa(u; \omega) \}_{h} \quad \text{satisfy the following conditions:} \quad \sup_{u \in [0,1]} | \kappa(u; h) | \leq C |h|^{-2 + \epsilon} \quad (\text{for} \quad h \neq 0, \quad \text{some} \quad \epsilon > 0 \quad \text{and finite constant} \quad C) \quad \text{and} \quad \sup_{u \in [0,1]} \sum h^2 | \frac{\partial \kappa(u; h)}{\partial u} | \leq C, \quad \text{where on the boundary} \quad 0 \quad \text{and} \quad 1 \quad \text{we use the right and left derivative} \quad (\text{this assumption can be relaxed to} \quad \kappa(u; h) \quad \text{being piecewise continuous, where within each piece the function has a bounded first and second derivative}). \quad \text{The function} \quad \{ \kappa(h) \} \quad \text{satisfies} \quad \sum h \kappa(h) < \infty.
\]

(L3) For some \( s > \frac{4\alpha - 6}{\alpha} > 0 \) with \( \alpha \) such that (3.7) holds, we have \( \sup_{t,T} \| X_{s,t} \|_s < \infty \).

(L4) Let \( f(u; \omega) = \frac{1}{2\pi} \sum_{h=-\infty}^{\infty} \kappa(u; h) \exp(-ih\omega) \). Then the integrated spectral density \( f(\omega) = \int_0^1 f(u; \omega) du \) is non-singular on \([0, 2\pi] \). Note that (L2) implies that \( \sup_{u} | \frac{\partial f(u; \omega)}{\partial u} | \leq C \).

(L5) For some \( s > \frac{8\alpha - 6}{\alpha - 2} > 0 \) with \( \alpha \) such that (3.7) holds, we have \( \sup_{t,T} \| X_{s,t} \|_s < \infty \).

As in the stationary case, it can be shown that several nonlinear time series satisfy Assumption 3.2 (L1) (cf. Fryzlewicz and Subba Rao (2011) and Vogt (2012) who derive sufficient conditions for \( \alpha \)-mixing of a general class of nonstationary time series). Assumption 3.2(L2) is used to show that the covariance changes slowly over time (these assumptions are used in order to derive the limit of the DFT covariance under local stationarity). It is worth pointing out that Assumption 3.2(L2) means that the error of approximation between the covariance of a locally stationary process \( \text{cov}(X_{1,T}, X_{2,T}) \) and the approximating stationary covariance \( \kappa(\frac{t_1 - t_2}{2}, t_1 - t_2) \) decays as the distance \( |t_1 - t_2| \) grows. This may appear counter intuitive, but our explanation for this assumption is that that the covariances \( \text{cov}(X_{1,T}, X_{2,T}) \) and \( \kappa(\frac{t_1 - t_2}{2}, t_1 - t_2) \) decay to zero as \( |t_1 - t_2| \rightarrow \infty \), therefore a bound for the difference between the two should reflect this decay. The stronger Assumption (L5) is required to replace \( \hat{L}(\omega) \) with its deterministic limit (see below for the limit).
3.3.2 Sampling properties of $\hat{C}_T(r, \ell)$ under local stationarity

As in the stationary case, it is difficult to directly analyze $\hat{C}_T(r, \ell)$. Therefore, we show that it can be replaced by $\hat{C}_T(r, \ell)$ (defined in (3.1)), where in the locally stationary case $L(\omega)$ are lower-triangular Cholesky matrices which satisfy $\overline{L(\omega)} L(\omega) = f^{-1}(\omega)$ and $f(\omega) = \int_0^1 f(u; \omega) du$.

**Theorem 3.5 (Asymptotic equivalence of $\hat{C}_T(r, \ell)$ and $\tilde{C}_T(r, \ell)$ under local stationarity)** Suppose Assumption 2.1 and 3.2 are satisfied and let $\hat{C}_T(r, \ell)$ and $\tilde{C}_T(r, \ell)$ be defined as in (2.6) and (3.1), respectively. Then we have

$$\sqrt{T} \hat{C}_T(r, \ell) = \sqrt{T} \left( \tilde{C}_T(r, \ell) + \mathcal{S}_T(r, \ell) + \mathcal{B}_T(r, \ell) \right) + O_P \left( \frac{\log T}{b \sqrt{T}} + b \log T + b^2 \sqrt{T} \right)$$

and

$$\mathcal{C}_T(r, \ell) = E(\mathcal{C}_T(r, \ell)) + o_p(1),$$

where $\mathcal{B}_T(r, \ell) = O(b)$ and $\mathcal{S}_T(r, \ell)$ are a deterministic bias and a stochastic term, respectively, which are defined in Appendix A.2, equation (A.8).

**Remark 3.2** There are some subtle differences between Theorems 3.1 and 3.5. In particular, the inclusion of the additional terms $\mathcal{S}_T(r, \ell)$ and $\mathcal{B}_T(r, \ell)$. We give a rough justification for this difference in the univariate case ($d = 1$). By taking differences, it can be shown that

$$\hat{C}_T(r, \ell) - \tilde{C}_T(r, \ell) \approx \frac{1}{T} \sum_{k=1}^T E \left( J_T(\omega_k) J_T(\omega_{k+1}) \right) \left[ \hat{f}_{k,r} - E(\hat{f}_{k,r}) \right] G(\omega_k)$$

$$+ \frac{1}{T} \sum_{k=1}^T E \left( J_T(\omega_k) J_T(\omega_{k+1}) \right) \left[ E(\hat{f}_{k,r}) - \hat{f}_{k,r} \right] G(\omega_k),$$

where $\hat{f}_{k,r} = (\hat{f}(\omega_k), \hat{f}(\omega_{k+1}))'$, $f_{k,r} = (f(\omega_k), f(\omega_{k+1}))'$ and $G(\omega_k)$ is defined in Lemma A.3 (see Appendix A.2 for the details). In the case of second order stationarity, since $E(J_T(\omega_k) J_T(\omega_{k+1})) = O(T^{-1})$ (for $r \neq 0$), the above terms are negligible, whereas in the case that the time series is nonstationary, $E(J_T(\omega_k) J_T(\omega_{k+1}))$ is no longer negligible. In the nonstationary univariate case, the $\mathcal{S}_T(r, \ell)$ and $\mathcal{B}_T(r, \ell)$ become

$$\mathcal{S}_T(r, \ell) = -\frac{1}{2T} \sum_{t, \tau=1}^T \lambda_0(t - \tau)(X_t X_{t+r} - E(X_t X_{t+r})$$

$$\times \frac{1}{T} \sum_{k=1}^T h(\omega_k; r) e^{i\omega_k} \left( \frac{e^{-i(t-\tau)\omega_k}}{\sqrt{f(\omega_k)^2 f(\omega_{k+r})}} + \frac{e^{-i(t-\tau)\omega_{k+r}}}{\sqrt{f(\omega_k) f(\omega_{k+r})}} \right) + O \left( \frac{1}{T} \right)$$

$$\mathcal{B}_T(r, \ell) = -\frac{1}{2T} \sum_{k=1}^T h(\omega_k, r) \left( \frac{E(\hat{f}_T(\omega_k)) - f(\omega_k)}{E(\hat{f}_T(\omega_k)) - f(\omega_{k+r})} \right)^' A(\omega_k, \omega_{k+r}),$$

where $A(\omega_k, \omega_{k+r})$ is a deterministic bias and $A(\omega_k, \omega_{k+r}) = O(1/T)$. Therefore, we show that it can be replaced by $\hat{C}_T(r, \ell)$ (defined in (3.1)), where in the locally stationary case $L(\omega)$ are lower-triangular Cholesky matrices which satisfy $\overline{L(\omega)} L(\omega) = f^{-1}(\omega)$ and $f(\omega) = \int_0^1 f(u; \omega) du$. 

**Theorem 3.5 (Asymptotic equivalence of $\hat{C}_T(r, \ell)$ and $\tilde{C}_T(r, \ell)$ under local stationarity)** Suppose Assumption 2.1 and 3.2 are satisfied and let $\hat{C}_T(r, \ell)$ and $\tilde{C}_T(r, \ell)$ be defined as in (2.6) and (3.1), respectively. Then we have

$$\sqrt{T} \hat{C}_T(r, \ell) = \sqrt{T} \left( \tilde{C}_T(r, \ell) + \mathcal{S}_T(r, \ell) + \mathcal{B}_T(r, \ell) \right) + O_P \left( \frac{\log T}{b \sqrt{T}} + b \log T + b^2 \sqrt{T} \right)$$

and

$$\mathcal{C}_T(r, \ell) = E(\mathcal{C}_T(r, \ell)) + o_p(1),$$

where $\mathcal{B}_T(r, \ell) = O(b)$ and $\mathcal{S}_T(r, \ell)$ are a deterministic bias and a stochastic term, respectively, which are defined in Appendix A.2, equation (A.8).
where

\[ \mathcal{A}(\omega_k, \omega_{k+r}) = \left( \frac{1}{(f(\omega_k))^2 J(\omega_{k+r})^{1/2}} \mathcal{H}(\omega_k f(\omega_{k+r})) \right) \]

and \( h(\omega; r) = \int_0^1 f(u; \omega) \exp(2\pi i u r) du \) (see Lemma A.7 for details). A careful analysis will show that \( S_T(r, \ell) \) and \( \tilde{C}_T(r, \ell) \) are both quadratic forms of the same order, this allows us to show asymptotic normality of \( \tilde{C}_T(r, \ell) \) under local stationarity.

**Lemma 3.1** Suppose Assumption 3.2 is satisfied. Then, for all \( r \in \mathbb{Z} \) and \( \ell \in \mathbb{Z} \), we have

\[ E(\tilde{C}_T(r, \ell)) \to A(r, \ell), \quad \text{and} \quad \tilde{C}_T(r, \ell) \overset{P}{\to} A(r, \ell) \]
as \( T \to \infty \), where

\[ A(r, \ell) = \frac{1}{2\pi} \int_0^{2\pi} \int_0^1 L(\omega) f(u; \omega) \overline{L(\omega)} \exp(i2\pi ru) \exp(i\ell \omega) du d\omega. \]  

(3.9)

Since \( \tilde{C}_T(r, \ell) \) is an estimator of \( A(r, \ell) \), we now discuss how to interpret this.

**Lemma 3.2** Let \( A(r, \ell) \) be defined as in (3.9). Then, under Assumption 3.2(L2,L4), we have that

(i) \( L(\omega)f(u, \omega)\overline{L(\omega)} \) satisfies the representation

\[ L(\omega)f(u, \omega)\overline{L(\omega)} = \sum_{r, \ell \in \mathbb{Z}} A(r, \ell) \exp(-i2\pi ru) \exp(-i\ell \omega). \]

and, consequently, \( f(u, \omega) = B(\omega) \left( \sum_{r, \ell \in \mathbb{Z}} A(r, \ell) \exp(-i2\pi ru) \exp(-i\ell \omega) \right) \overline{B(\omega)}. \)

(ii) \( A(r, \ell) \) is zero for all \( r \neq 0 \) and \( \ell \in \mathbb{Z} \) iff \( \{X_t\} \) is second order stationary.

(iii) For all \( \ell \neq 0 \) and \( r \neq 0 \), \( |A(r, \ell)|_1 \leq K |r|^{-1} |\ell|^{-2} \) (for some finite constant \( K \)).

(iv) \( A(r, \ell) = A(-r, \ell) \).

We see from part (ii) of the above lemma that for \( r \neq 0 \), the coefficients \( \{A(r, \ell)\} \) characterize the nonstationarity. One consequence of Lemma 3.2 is that only for second order stationary time series, we have that

\[ \sum_{r=1}^m \sum_{\ell=0}^{n-1} \left( |S_{r, \ell} \text{vech}(\Re A(r, \ell))|^2 + |S_{r, \ell} \text{vech}(\Im A(r, \ell))|^2 \right) = 0 \]

(3.10)

for any non-singular matrices \( \{S_{r, \ell}\} \) and all \( n, m \in \mathbb{N} \). Therefore, under the alternative of local stationarity, the purpose of the test statistic is to detect the coefficients \( A(r, \ell) \). Lemma 3.2 highlights another crucial point, that is, under local stationarity \( |A(r, \ell)|_1 \) decays at the rate \( C |r|^{-1} |\ell|^{-2} \). Thus, the test will lose power if a large number of lags are used.
Theorem 3.6 (Limiting distributions of vech(\(\hat{K}_n(r)\))) Let us assume that Assumption 2.1 and 3.2 holds and let \(\hat{K}_n(r)\) be defined as in (2.8). Then, for fixed \(m, n \in \mathbb{N}\), we have

\[
\sqrt{T} \begin{pmatrix}
\Re \hat{K}_n(1) - \Re A_n(1) - \Re B_n(1) \\
\Im \hat{K}_n(1) - \Im A_n(1) - \Im B_n(1) \\
\vdots \\
\Re \hat{K}_n(m) - \Re A_n(m) - \Re B_n(m) \\
\Im \hat{K}_n(m) - \Im A_n(m) - \Im B_n(m)
\end{pmatrix} \xrightarrow{D} \mathcal{N}\left(\mathbf{0}_{\text{md}(d+1)}, \tilde{W}_{m,n}\right),
\]

where \(\tilde{W}_{m,n}\) is an \((\text{md}(d+1) \times \text{md}(d+1))\) covariance matrix (which is not necessarily block diagonal), \(A_n(r) = (\text{vech}(A(r, 0))^\prime, \ldots, \text{vech}(A(r, n-1))^\prime)^\prime\) are the vectorized Fourier coefficients and \(B_n(r) = (\text{vech}(B(r, 0))^\prime, \ldots, \text{vech}(B(r, n-1))^\prime)^\prime = O(b)\).

At this point it is interesting to point out that the quantity \(A(r, \ell)\) is closely related to the ‘Ambiguity function’ recently introduced in Hindberg and Olhede (2010). The ambiguity function is the Discrete Fourier transform over \(t\) of the empirical covariances at a given lag \(\ell\) (see equation (1) and in S. C. Olhede (2011)), whereas \(A(r, \ell)\) is the Fourier coefficient (over \(u\)) of

\[
\frac{1}{2\pi} \int_0^{2\pi} L(\omega) f(u; \omega) \overline{L(\omega)} \exp(i\ell\omega) d\omega.
\]

4 Properties of the stationary bootstrap applied to stationary and nonstationary time series

In this section, we consider the moments and cumulants of observations sampled using the stationary bootstrap and its corresponding discrete Fourier transform. We use these results to analyze the bootstrap procedure proposed in Section 2.4. In order to reduce unnecessary notation, we state the results in this section for the univariate case only (all these results easily generalize to the multivariate case). The results in this section may also be of independent interest as they compare the differing characteristics of the stationary bootstrap when the underlying process is stationary and nonstationary. For this reason, this section is self-contained, where the main assumptions are mixing and moment conditions. The justification for the use of these mixing and moment conditions can be found in the proof of Lemma 4.1 (see Appendix A.5).

We start by defining the cyclical and the ordinary sample covariances for \(0 \leq h \leq T - 1\)

\[
\hat{\kappa}^C(h) = \frac{1}{T} \sum_{t=1}^{T} Y_t Y_{t+h} - (\overline{X})^2, \quad \hat{\kappa}(h) = \frac{1}{T} \sum_{t=1}^{T-h} X_t X_{t+h} - (\overline{X})^2,
\]

respectively, where \(Y_t = X_{(t-1)\text{mod } T+1}\) and \(\overline{X} = \frac{1}{T} \sum_{t=1}^{T} X_t\). We will also consider the higher order
cumulants. Therefore we define the corresponding sample moments for $0 \leq h_1, \ldots, h_{n-1} \leq T - 1$ as

$$
\hat{\kappa}_n^C(h_1, \ldots, h_{n-1}) = \frac{1}{T} \sum_{t=1}^{T} Y_t \prod_{i=1}^{n-1} Y_{t+h_i}, \quad \hat{\mu}_n(h_1, \ldots, h_{n-1}) = \frac{1}{T} \sum_{t=1}^{T} X_t \prod_{i=1}^{n-1} X_{t+h_i},
$$

(4.1)

where the notation $\max(h_i) = \max\{h_1, \ldots, h_{n-1}\}$ is used, and the $n$th order cumulants corresponding to these moments

$$
\hat{\kappa}_n^C(h_1, \ldots, h_{n-1}) = \sum_{\pi} (|\pi| - 1)!(\bar{-1})^{|\pi|-1} \prod_{B \in \pi} \hat{\mu}_n(B),
$$

(4.2)

$$
\hat{\kappa}_n^C(h_1, \ldots, h_{n-1}) = \sum_{\pi} (|\pi| - 1)!(\bar{-1})^{|\pi|-1} \prod_{B \in \pi} \hat{\mu}_n(B),
$$

(4.3)

where $\pi$ runs through all partitions of $\{0, h_1, \ldots, h_{n-1}\}$, $B$ are the blocks in the partition $\pi$ and $|B|$ denotes the cardinality of the set $B$. We note these definitions are invariant to the ordering of the $\{h_1, \ldots, h_{n-1}\}$.

We now define the sampling cumulants in the case that $h_i < 0$. Since the cumulants are invariant to ordering we will assume that $h_1 \leq h_2 \leq \ldots \leq h_{n-1}$. If $h_1 < 0$ and $h_{n-1} - h_1 \leq T - 1$, then we set $\hat{\kappa}_n(h_1, \ldots, h_{n-1}) = \hat{\kappa}_n(-h_1, h_2 - h_1, \ldots, h_{n-1} - h_1)$. If $h_1 \geq 0$ and $h_{n-1} > T - 1$ or $h_1 < 0$ and $h_{n-1} - h_1 > T - 1$, then we set $\hat{\kappa}_n(h_1, \ldots, h_{n-1}) = 0$. $\hat{\kappa}_n^C(h_1, \ldots, h_{n-1})$ is defined in a similar way for $h_1 < 0$. In order to obtain an expression for the cumulant of the DFT, we require the following lemma.

We note that $E^*$, $\text{cov}^*$ and $\text{cum}^*$ denote the expectation, covariance and cumulant with respect to the stationary bootstrap measure defined in Step 2 of Section 2.4.

**Lemma 4.1** Let $\{X_t\}$ be a time series with constant mean and $\sup_t E|X_t|^n < \infty$. Let $\hat{\mu}_n(h_1, \ldots, h_{n-1})$ be defined as in (4.1). We define the following expected quantities. For $0 \leq h_1, \ldots, h_{n-1} \leq T - 1$, let

$$
\tilde{\kappa}_n(h_1, \ldots, h_{n-1}) = \sum_{\pi} (|\pi| - 1)!(\bar{-1})^{|\pi|-1} \prod_{B \in \pi} E[\hat{\mu}_n(B)],
$$

(4.3)

where $\pi$ runs through all partitions of $\{0, h_1, \ldots, h_{n-1}\}$. Further, define

$$
\tilde{\kappa}_n(h_1, \ldots, h_{n-1}) = \sum_{\pi} (|\pi| - 1)!(\bar{-1})^{|\pi|-1} \prod_{B \in \pi} \left( \frac{1}{T} \sum_{t=1}^{T} E(X_{t+i_1}X_{t+i_2} \ldots X_{t+i_{|B|}}) \right),
$$

(4.4)

where $B = \{i_1, \ldots, i_{|B|}\}$. $\tilde{\kappa}_n(h_1, \ldots, h_{n-1})$ is defined in a similar way to $\hat{\kappa}_n(h_1, \ldots, h_{n-1})$ for $h_1 < 0$.

(i) Suppose that $0 \leq t_1 \leq t_2 \leq \ldots \leq t_{n-1}$, then

$$
\text{cum}^* (X_1^*, X_{t_1}^*, \ldots, X_{t_{n-1}}^*) = (1 - p)^{t_{n-1}} \hat{\kappa}_n^C(t_1, \ldots, t_{n-1}).
$$

To prove the assertions (ii-iv) below, we require the additional assumption that the time series $\{X_t\}$ is $\alpha$-mixing, where for a given $q \geq 2n$ we have $\alpha > q$ and for some $r > q\alpha/(\alpha - q/n)$ we have $\sup_t \|X_t\|_r < \infty$. Note that this is a technical assumption that is used to give the following moment bounds, the exact details for their use can be found in the proof. Without loss of generality we will assume that $0 \leq h_1 \leq h_2 \leq \ldots \leq h_{n-1}$. 

22
(ii) Approximation of circulant cumulant $\tilde{\kappa}^C$ by regular sample cumulant. We have

$$||\tilde{\kappa}_n^C(h_1, \ldots, h_{n-1}) - \bar{\kappa}_n(h_1, \ldots, h_{n-1})||_{q/n} \leq C \frac{h_{n-1}}{T} \sup_{t} ||X_t||_q^n,$$  \hspace{1cm} (4.5)

where $C$ is a finite constant which only depends on the order of the cumulant.

(iii) Approximation of regular sample cumulant by ‘the cumulant of averages’. We have

$$||\tilde{\kappa}_n(h_1, \ldots, h_{n-1}) - \bar{\kappa}_n(h_1, \ldots, h_{n-1})||_{q/n} = O(T^{-1/2})$$  \hspace{1cm} (4.6)

and, for some finite constant $C$,

$$|\tilde{\kappa}_n(h_1, \ldots, h_{n-1}) - \bar{\kappa}_n(h_1, \ldots, h_{n-1})| \leq C \frac{h_{n-1}}{T}.$$  \hspace{1cm} (4.7)

(iv) In the case of $n$th order stationarity, it is clear that $\bar{\kappa}_n(h_1, \ldots, h_{n-1}) = \text{cum}(X_t, X_{t+h_1}, \ldots, X_{t+h_{n-1}})$.

However, if the time series is nonstationary, then

(a) $\bar{\kappa}_2(h) = \frac{1}{T} \sum_{t=1}^T \text{cov}(X_t, X_{t+h})$

(b) $\bar{\kappa}_3(h_1, h_2) = \frac{1}{T} \sum_{t=1}^T \text{cum}(X_t, X_{t+h_1}, X_{t+h_2})$

(c) The situation is different for the fourth order cumulant and we have

$$\bar{\kappa}_4(h_1, h_2, h_3) = \frac{1}{T} \sum_{t=1}^T \text{cum}(X_t, X_{t+h_1}, X_{t+h_2}, X_{t+h_3})$$

$$+ \frac{1}{T} \sum_{t=1}^T \text{cov}(X_t, X_{t+h_1}) \text{cov}(X_{t+h_2}, X_{t+h_3}) - \left( \frac{1}{T} \sum_{t=1}^T \text{cov}(X_t, X_{t+h_1}) \right) \left( \frac{1}{T} \sum_{t=1}^T \text{cov}(X_{t+h_2}, X_{t+h_3}) \right)$$

$$+ \frac{1}{T} \sum_{t=1}^T \text{cov}(X_t, X_{t+h_2}) \text{cov}(X_{t+h_1}, X_{t+h_3}) - \left( \frac{1}{T} \sum_{t=1}^T \text{cov}(X_t, X_{t+h_2}) \right) \left( \frac{1}{T} \sum_{t=1}^T \text{cov}(X_{t+h_1}, X_{t+h_3}) \right)$$

$$+ \frac{1}{T} \sum_{t=1}^T \text{cov}(X_t, X_{t+h_3}) \text{cov}(X_{t+h_1}, X_{t+h_2}) - \left( \frac{1}{T} \sum_{t=1}^T \text{cov}(X_t, X_{t+h_3}) \right) \left( \frac{1}{T} \sum_{t=1}^T \text{cov}(X_{t+h_1}, X_{t+h_2}) \right)$$  \hspace{1cm} (4.8)

(d) A similar expansion holds for $\bar{\kappa}_n(h_1, \ldots, h_{n-1})$ ($n > 4$), i.e. $\bar{\kappa}_n(\cdot)$ can be written as the average $n$th order cumulants plus additional lower order average cumulants terms.

In the above lemma we have shown that for stationary time series, the bootstrap cumulant is an approximation of the corresponding cumulant of the time series, which is not surprising. However, in the nonstationary case the bootstrap cumulant behaves differently. Under the assumption that the mean of the nonstationary time series is constant, the bootstrap cumulant of both second and third orders are the averages of the corresponding local cumulants. In other words, the second and third order bootstrap
cumulants of a nonstationary time series behave like a stationary cumulant, i.e. there is a decay in the cumulant the further apart the time lag. However, the bootstrap cumulants of higher orders (fourth and above) is not the average of the local cumulants, there are additional terms (see (4.8)). This means that the cumulants do not have the same decay as regular cumulants have. For example, from equation (4.8) we see that as the difference \( |h_1 - h_2| \to \infty \), the function \( \tilde{\kappa}_4(h_1, h_2, h_3) \) does not converge to zero, whereas \( \text{cum}(X_t, X_{t+h_1}, X_{t+h_2}, X_{t+h_3}) \) does (see Lemma A.9, in the Appendix).

We use Lemma 4.1 to derive results analogous to Brillinger (1981), Theorem 4.3.2, where an expression for the cumulant of DFTs in terms of the higher order spectral densities was derived. However, to prove this result we first need to derive the limit of the Fourier transform of the cumulant estimators. We define the sample higher order spectral density function as

\[
\hat{h}_n(\omega_1, \ldots, \omega_{n-1}) = \frac{1}{(2\pi)^{n-1}} \sum_{\text{max}(h_i, 0) - \min(h_i, 0)}^{(T-1)} \sum_{h_1, \ldots, h_{n-1} = -(T-1)} \cdot (1 - p)^{\text{max}(h_i, 0) - \min(h_i, 0)} \tilde{\kappa}_n(h_1, \ldots, h_{n-1}) e^{-ih_1\omega_1 - \ldots - ih_{n-1}\omega_{n-1}},
\]

where \( \tilde{\kappa}_n(\cdot) \) are the sample cumulants defined in (4.2). In the following lemma, we show that \( \hat{h}_n(\cdot) \) approximates the ‘pseudo’ higher order spectral density

\[
f_{n,T}(\omega_1, \ldots, \omega_{n-1}) = \frac{1}{(2\pi)^{n-1}} \sum_{\text{max}(h_i, 0) - \min(h_i, 0)}^{(T-1)} \sum_{h_1, \ldots, h_{n-1} = -(T-1)} \cdot (1 - p)^{\text{max}(h_i, 0) - \min(h_i, 0)} \tilde{\kappa}_n(h_1, \ldots, h_{n-1}) e^{-ih_1\omega_1 - \ldots - ih_{n-1}\omega_{n-1}},
\]

where \( \tilde{\kappa}_n(\cdot) \) is defined in (4.4).

We now show that under certain conditions \( \hat{h}_n(\cdot) \) is an estimator of the higher order spectral density function.

**Lemma 4.2** Suppose the time series \( \{X_t\} \) (where \( \text{E}(X_t) = \mu \) for all \( t \)) is \( \alpha \)-mixing and \( \sup_t \|X_t\|_r < \infty \) for some \( r > q\alpha/(\alpha - q/n) \) (and \( \alpha > q \)).

(i) Let \( \hat{h}_n(\cdot) \) and \( f_{n,T}(\cdot) \) be defined in (4.9) and (4.10), respectively. Then we have

\[
\sup_{\omega_1, \ldots, \omega_{n-1}} \left\| \hat{h}_n(\omega_1, \ldots, \omega_{n-1}) - f_{n,T}(\omega_1, \ldots, \omega_{n-1}) \right\|_{q/n} = O \left( \frac{1}{T^{p^n}} + \frac{1}{T^{1/2}p(n-1)} \right),
\]

(ii) If the time series is \( n \)th order stationary which is \( \alpha \)-mixing with rate \( \alpha > 2r(n-1)/(r-n) \) (we use this bound to obtain a rate of decay on the \( n \)th order cumulant), then we have

\[
\sup_{\omega_1, \ldots, \omega_{n-1}} \left\| \hat{h}_n(\omega_1, \ldots, \omega_{n-1}) - f_n(\omega_1, \ldots, \omega_{n-1}) \right\|_{q/n} = O \left( \frac{1}{T^{p^n}} + \frac{1}{T^{1/2}p(n-1) + p} \right)
\]
and $\sup_{\omega_1, \ldots, \omega_{n-1}} |f_n(\omega_1, \ldots, \omega_{n-1})| < \infty$, where $f_n$ is the nth order spectral density function defined as

$$f_n(\omega_1, \ldots, \omega_{n-1}) = \frac{1}{(2\pi)^{n-1}} \sum_{h_1, \ldots, h_{n-1} = -\infty}^{\infty} \kappa_n(h_1, \ldots, h_{n-1}) e^{-ih_1\omega_1 - \cdots - ih_{n-1}\omega_{n-1}}$$

and $\kappa_n(h_1, \ldots, h_{n-1}) = \text{cum}(X_0, X_{h_1}, \ldots, X_{h_{n-1}})$ denotes the nth order joint cumulant of the stationary time series $\{X_t\}$.

(iii) On the other hand, if the time series is nonstationary:

(a) For $n \in \{2, 3\}$, we have

$$\sup_{\omega} \left\| \tilde{h}_2(\omega) - f_{2,T}(\omega) \right\|_{q/n} = O\left(\frac{1}{T^{p^2}} + \frac{1}{T^{1/2}p}\right),$$

$$\sup_{\omega_1, \omega_2} \left\| \tilde{h}_3(\omega_1, \omega_2) - f_{3,T}(\omega_1, \omega_2) \right\|_{q/n} = O\left(\frac{1}{T^{p^3}} + \frac{1}{T^{1/2}p^2}\right),$$

where $f_{2,T}(\omega) = \frac{1}{2\pi} \sum_{h=-\infty}^{\infty} \tilde{h}_2(h) \exp(ih\omega)$ with $\tilde{h}_2(h)$ defined as in Lemma 4.1(iv) and $f_{3,T}$ is defined similarly. Since the average covariances and cumulants are absolutely summable, we have $\sup_{T,\omega} |f_{2,T}(\omega)| < \infty$ and $\sup_{T,\omega_1, \omega_2} |f_{3,T}(\omega_1, \omega_2)| < \infty$.

(b) For $n = 4$, we have $\sup_{\omega_1, \omega_2, \omega_3} |f_{4,T}(\omega_1, \omega_2, \omega_3)| = O(p^{-1})$.

(c) For $n \geq 4$, we have $\sup_{\omega_1, \ldots, \omega_{n-1}} |f_{n,T}(\omega_1, \ldots, \omega_{n-1})| = O(p^{-(n-3)})$.

The following result is the bootstrap analogue of (Brillinger, 1981), Theorem 4.3.2.

**Theorem 4.1** Let $J_T^r(\omega)$ denote the DFT of the stationary bootstrap observations. Under the assumption that $\sup_t \|X_t\|_n < \infty$, we have

$$\|\text{cum}^*(J_T^r(\omega_{k_1}), \ldots, J_T^r(\omega_{k_n}))\|_1 = O\left(\frac{1}{T^{n/2-1}p^{n-1}}\right).$$

(4.13)

By imposing the additional condition that $\{X_t\}$ is an $\alpha$-mixing time series with a constant mean, $q/n \geq 2$, the mixing rate $\alpha > q$ and $\|X_t\|_r < \infty$ for some $r > qa/(\alpha - q/n)$, we obtain

$$\text{cum}^*(J_T^r(\omega_{k_1}), \ldots, J_T^r(\omega_{k_n})) = \left(\frac{2\pi)^{n/2-1}}{T^{n/2-1}} \tilde{h}_n(\omega_{k_1}, \ldots, \omega_{k_{n-1}}) \frac{1}{T} \sum_{t=1}^{T} \exp(-it(\omega_{k_1} + \cdots + \omega_{k_{n-1}})) + R_{T,n},$$

(4.14)

where $\|R_{T,n}\|_{q/n} = O\left(\frac{1}{T^{1/2}p^n}\right)$.
(a) If \( \{X_t\} \) is \( n \)th order stationary which is \( \alpha \)-mixing with rate \( \alpha > 2r(n-1)/(r-n) \), then we have
\[
\text{cum}^*\left(J^*_T(\omega_{k_1}), \ldots, J^*_T(\omega_{k_n})\right) = \frac{(2\pi)^{n/2-1}}{T^{n/2-1}} f_n(\omega_{k_1}, \ldots, \omega_{k_{n-1}}) \frac{1}{T} \sum_{t=1}^{T} \exp(-it(\omega_{k_1} + \ldots + \omega_{k_n})) + R_{T,n}
\]
\[
= \begin{cases} 
O\left(\frac{1}{T^{n/2-1}} + \frac{1}{(f_1/2)^n}\right), & \sum_{l=1}^{n} \omega_{k_l} \in 2\pi\mathbb{Z}, \\
O\left(\frac{1}{(f_1/2)^n}\right), & \sum_{l=1}^{n} \omega_{k_l} \notin 2\pi\mathbb{Z},
\end{cases}
\tag{4.15}
\]
which is uniform over \( \{\omega_{k_1}, \ldots, \omega_{k_n}\} \) and \( \|R_{T,n}\|_{q/n} = O\left(\frac{1}{(f_1/2)^n}\right) \).

(b) If \( \{X_t\} \) is nonstationary (with constant mean) then for \( n \in \{2, 3\} \), we can replace \( f_n \) with \( f_{2,T} \) and \( f_{3,T} \) in (4.15), respectively, and obtain the same as above.

For \( n \geq 4 \), we have
\[
\|\text{cum}^*\left(J^*_T(\omega_{k_1}), \ldots, J^*_T(\omega_{k_n})\right)\|_{q/n} = \begin{cases} 
O\left(\frac{1}{T^{n/2-1}} + \frac{1}{(f_1/2)^n}\right), & \sum_{l=1}^{n} \omega_{k_l} \in 2\pi\mathbb{Z}, \\
O\left(\frac{1}{(f_1/2)^n}\right), & \sum_{l=1}^{n} \omega_{k_l} \notin 2\pi\mathbb{Z},
\end{cases}
\tag{4.16}
\]

A very useful consequence of the above theorem is that the stationary bootstrap can be used to estimate the \( n \)th order spectral density. More precisely, suppose \( \{X_t\} \) is an \( n \)th order stationary time series which satisfies the assumptions of Theorem 4.1(a) above, then for \( \omega_{k_1} + \ldots + \omega_{k_n} \in 2\pi\mathbb{Z} \) we have
\[
\frac{T^{n/2-1}}{(2\pi)^{n/2-1}} \text{cum}^*\left(J^*_T(\omega_{k_1}), \ldots, J^*_T(\omega_{k_n})\right) = f_n(\omega_{k_1}, \ldots, \omega_{k_{n-1}}) + O_p\left(\frac{1}{T^{p^n}}\right)
\]
In other words by evaluating the empirical cumulant of the stationary bootstrap samples of DFTs we obtain an estimator of the \( n \)th order spectral density function. We observe that \( p \) plays the role of a bandwidth.

On the other hand, if \( \{X_t\} \) is a nonstationary time series (with a constant mean), then for \( n \geq 4 \) we have that
\[
\frac{T^{n/2-1}}{(2\pi)^{n/2-1}} \text{cum}^*\left(J^*_T(\omega_{k_1}), \ldots, J^*_T(\omega_{k_n})\right) = O_p\left(\frac{1}{n^{p-3}}\right).
\]

Note that if \( \{X_t\} \) has a time dependent mean, then the above result is true for \( n \geq 2 \).

5 Analysis of the test statistic

In Section 3.1, we derived the properties of the DFT covariance in the case of stationarity. These results show that the distribution of the test statistic, in the unlikely event that \( W^{(2)} \) is known, is a chi-square (see Theorem 3.4). In the case that \( W^{(2)} \) is unknown as in Section 2.4 we proposed a method to estimate \( W^{(2)} \) and thus the bootstrap statistic. In this section we show that under fourth order stationarity of the time series, the bootstrap variance defined in Step 6 of the algorithm is a consistent estimator of \( W^{(2)} \). Thus,
the bootstrap statistic $T^*_{m,n,d}$ asymptotically converges to a chi-squared distribution. We also investigate the power of the test under the alternative of local stationarity. To derive the power, we use the results in Section 3.3, where we show that for at least some values of $r$ and $\ell$ (usually the low orders), $\hat{C}_T(r, \ell)$ has a non-centralized normal distribution. However, the test statistic also involves $W^{(2)}$, which is estimated as if the underlying time series is stationary (using the stationary bootstrap procedure). Therefore, in this section, we derive an expression for the quantity that $\hat{C}_T(r, \ell)$ is estimating under the assumption of second order nonstationarity, and explain how this influences the power of the test.

We use the following assumption in Lemma 5.1, where we show that the variances of the bootstrap cumulants converge to zero as the sample size increases.

**Assumption 5.1** Suppose that $\{X_t\}$ is $\alpha$-mixing with $\alpha > 8$ and the moments satisfy $\|X_t\|_s < \infty$, where $s > 8\alpha/(\alpha - 2)$.

**Lemma 5.1** Suppose that the time series $\{X_t\}$ satisfies Assumption 5.1.

(i) $\{X_t\}$ is fourth order stationary, then we have

(a) $\text{cum}^*(J_{r,j_1}^*(\omega_1), J_{r,j_2}^*(\omega_2)) = f_{j_1,j_2}(\omega_1)I(k_1 = -k_2) + R_{1,T}$.

(b) $\text{cum}^*(J_{r,j_1}^*(\omega_1), J_{r,j_2}^*(\omega_2), J_{r,j_3}^*(\omega_3), J_{r,j_4}^*(\omega_4)) = \frac{2\pi}{T} f_{j_1,\ldots,j_4}(\omega_1, \omega_2, \omega_3, \omega_4)I(k_1 = -k_2 = -k_3) + R_{2,T}$,

where $\|R_{1,T}\|_4 = O\left(\frac{1}{T^p}\right)$ and $\|R_{2,T}\|_2 = O\left(\frac{1}{T^p}\right)$

(ii) $\{X_t\}$ has a constant mean, but it is not fourth order stationary, then we have

(a) $\text{cum}^*(J_{r,j_1}^*(\omega_1), J_{r,j_2}^*(\omega_2)) = f_{2,T; j_1,j_2}(\omega_1)I(k_1 = -k_2) + R_{1,T}$

(b) $\text{cum}^*(J_{r,j_1}^*(\omega_1), J_{r,j_2}^*(\omega_2), J_{r,j_3}^*(\omega_3), J_{r,j_4}^*(\omega_4)) = \frac{2\pi}{T} f_{4,T; j_1,\ldots,j_4}(\omega_1, \omega_2, \omega_3, \omega_4)I(k_1 = -k_2 = -k_3) + R_{2,T}$,

where $f_{2,T; j_1,j_2}(\omega_1)$ and $f_{4,T; j_1,\ldots,j_4}(\omega_1, \omega_2, \omega_3, \omega_4)$ are multivariate analogues of (4.10), $\|R_{1,T}\|_4 = O\left(\frac{1}{T^p}\right)$ and $\|R_{2,T}\|_2 = O\left(\frac{1}{T^p}\right)$.

In order to obtain the limit of the bootstrap variance estimator, we define

$$\hat{C}_T^*(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} L(\omega_k)J_{r,k}^*(\omega_k)J_{r,k+r}^*(\omega_{k+r}) \exp(i\ell \omega_k).$$

We observe that this is almost identical to the bootstrap DFT $\hat{C}_T^*(r, \ell)$ and $C_T^*(r, \ell)$, except that $\hat{L}^*(\cdot)$ and $\hat{L}(\cdot)$ have been replaced with their limit $L(\cdot)$. We first obtain the variance of $\hat{C}_T^*(r, \ell)$, which is simple a consequence of Lemma 5.1. Later, we show that it is equivalent to the bootstrap variances of $\hat{C}_T^*(r, \ell)$ and $\hat{C}_T^*(r, \ell)$. 

27
Theorem 5.1 (Consistency of the variance estimator based on $\hat{C}_T^*(r, \ell)$) Suppose that $\{X_t\}$ is an $\alpha$-mixing time series which satisfies Assumption 5.1 and let

$$\hat{K}_n^*(r) = \left(\text{vech}(\hat{C}_T^*(r, 0)), \text{vech}(\hat{C}_T^*(r, 1)), \ldots, \text{vech}(\hat{C}_T^*(r, n-1))\right)^\prime.$$ \hfill (B1)

Suppose $T \to \infty$, $b T p^2 \to \infty$, $b \to 0$ and $p \to 0$ as $T \to \infty$.

(i) In addition suppose that $\{X_t\}$ is a fourth order stationary time series. Let $W_n$ be defined as in (2.14). Then for fixed $m, n \in \mathbb{N}$ we have $\text{Var}^*(\hat{\Re}K_n^*(r)) = W_n + o_p(1)$ and $\text{Var}^*(\hat{\Im}K_n^*(r)) = W_n + o_p(1)$.

(ii) On the other hand, suppose $\{X_t\}$ is a locally stationary time series which satisfies Assumption 3.2(L2). Let

$$\kappa_T^{(\ell_1, \ell_2)}(j_1, j_2, j_3, j_4) = \frac{2\pi}{T^2} \sum_{k_1, k_2 = 1}^T \sum_{s_1, s_2, s_3, s_4 = 1}^T L_{j_1, s_1}(\omega_{k_1}) L_{j_2, s_2}(\omega_{k_1}) L_{j_3, s_3}(\omega_{k_2}) L_{j_4, s_4}(\omega_{k_2}) \times \exp(i \ell_1 \omega_{k_1} - i \ell_2 \omega_{k_2}) \int_{t_1}^{t_2} f_{4, T; s_1, s_2, s_3, s_4}(\omega_{k_1}, -\omega_{k_1}, -\omega_{k_2}, \omega_{k_2}^\prime) (1 - p)^{\max(h_1, 0) - \min(h_i, 0)} \max(h_1, 0) - \min(h_i, 0) \leq T - 1 \exp(-i(h_1 \lambda_1 + h_2 \lambda_2 + h_3 \lambda_3)). \quad (5.1)$$

where $L(\omega) = f^{-1}(\omega)$, $f(\omega) = \int_0^1 f(u; \omega) du$ and

$$f_{4, T; s_1, s_2, s_3, s_4}(\lambda_1, \lambda_2, \lambda_3) = \frac{1}{(2\pi)^3} \sum_{h_1, h_2, h_3 = -1}^{T-1} (1 - p)^{\max(h_1, 0) - \min(h_1, 0)} \times \kappa_{4; s_1, s_2, s_3, s_4}(h_1, h_2, h_3) \exp(-i(h_1 \lambda_1 + h_2 \lambda_2 + h_3 \lambda_3)).$$

Using the above we define

$$(W_{T, n})_{\ell_1, \ell_2} = W_{\ell_1}^{(1)} \delta_{\ell_1, \ell_2} + W_{\ell_1, \ell_2}^{(2)}, \quad (5.2)$$

where $W_{\ell_1}^{(1)}$ and $W_{\ell_1, \ell_2}^{(2)}$ are defined as in (2.13) and (2.17) but with $\kappa_T^{(\ell_1, \ell_2)}(j_1, j_2, j_3, j_4)$ replaced with $\kappa_T^{(\ell_1, \ell_2)}(j_1, j_2, j_3, j_4)$. Then, for fixed $m, n \in \mathbb{N}$, we have $\text{Var}^*(\hat{\Re}K_n^*(r)) = W_{T, n} + o_p(1)$ and $\text{Var}^*(\hat{\Im}K_n^*(r)) = W_{T, n} + o_p(1)$. Furthermore, $|\kappa_T^{(\ell_1, \ell_2)}(j_1, j_2, j_3, j_4)| = O(p^{-1})$ and $|W_{T, n}| = O(p^{-1})$.

The above theorem shows that if $f(\omega)$ and consequently $\hat{C}_T^*(r, \ell)$ were known, then the bootstrap variance estimator is consistent under fourth order stationarity. Now we show that both the asymptotic bootstrap variances of $\hat{C}_T^*(r, \ell)$ and $\hat{C}_T^*(r, \ell)$ are asymptotically equivalent to the variance of $\hat{C}_T^*(r, \ell)$.

Assumption 5.2 (Variance equivalence) (B1) Let $\hat{f}_{\alpha, T}(\omega) = \alpha(\omega)\hat{f}_{\alpha}^*(\omega) + (1 - \alpha(\omega))\hat{f}_T(\omega)$, where $\alpha : [0, 2\pi] \to [0, 1]$ and $L_{j_1, j_2}(\cdot)$ denote the $(j_1, j_2)$th element of the matrix $L(\cdot)$. Let $\nabla^i L_{j_1, j_2}(f(\omega))$ denote the $i$th derivative with respect to vec$(f(\omega))$. We assume that for every $\varepsilon > 0$ there exists a $0 < M_\varepsilon \leq \infty$ such that

$$P\left(\sup_{\alpha, \omega} (E^*|\nabla^i L_{j_1, j_2}(\hat{f}_{\alpha, T}^*(\omega))|^8)^{1/8} > M_\varepsilon\right) < \varepsilon,$$
for $i = 0, 1, 2$. In other words the sequence $\{\sup_{\alpha, \omega}(E^*|\nabla^i L_{j_1, j_2}(\hat{f}^*_a(T(\omega)))|^8)^{1/8}\}_T$ is bounded in probability.

(B2) The time series $\{X_t\}$ is $\alpha$-mixing with $\alpha > 16$ and has a finite $s$th moment ($\sup_{t}||X_t||_s < \infty$) such that $s > 16\alpha/\alpha - 2$.

**Remark 5.1 (On Assumption 5.2(B1))**

(i) This is a technical assumption that is required when showing equivalence of the bootstrap variance estimator using $\hat{C}^*_T(r, \ell)$ to the bootstrap variance using $\tilde{C}^*_T(r, \ell)$. In the case we use $\hat{C}^*_T(r, \ell)$ to construct the bootstrap variance (defined in (2.26)) we do not require this assumption.

(ii) Let $\nabla^2$ denote the second derivative with respect to the vector $(\hat{f}^*_a(T(\omega_1)), \hat{f}^*_a(T(\omega_2)))$. Assumption 5.2(B1) implies that the sequence $\sup_{\omega_1, \omega_2, \alpha} E^*|\nabla^2 L_{j_1, j_2}(\hat{f}^*_a(T(\omega_1)))L_{j_1, j_2}(\hat{f}^*_a(T(\omega_2)))|^41/4$ is bounded in probability. We use this result in the proof of Lemma A.16.

(ii) In the case $d = 1$, $L(\omega) = f^{-1/2}(\omega)$ and Assumption 5.2(B1) corresponds to the condition that for $i = 0, 1, 2$ the sequence $\{\sup_{\alpha, \omega}[E^*(\hat{f}^*_a(T(\omega))^{-4(2i+1)})]^{1/8}\}_T$ is bounded in probability.

Using the assumptions above, we derive a bound for the difference between the covariances $\hat{C}^*_T(r, \ell)$ and $\tilde{C}^*_T(r, \ell)$.

**Lemma 5.2** Suppose that $\{X_t\}$ is a fourth order stationary time series or a constant mean locally stationary time series which satisfies Assumption 3.2(L2)), Assumption 5.2(B2) holds and $Tp^4 \rightarrow \infty$, $bTp^2 \rightarrow \infty$, $b \rightarrow 0$ and $p \rightarrow 0$ as $T \rightarrow \infty$. Then, we have

(i)

$$|T \left( \text{cov}^*(\Re\hat{C}^*_T(r, \ell_1), \Re\hat{C}^*_T(r, \ell_2)) - \text{cov}^*(\Re\hat{C}^*_T(r, \ell_1), \Re\tilde{C}^*_T(r, \ell_2)) \right) | = o_p(1).$$

and

$$|T \left( \text{cov}^*(\Im\hat{C}^*_T(r, \ell_1), \Im\hat{C}^*_T(r, \ell_2)) - \text{cov}^*(\Im\hat{C}^*_T(r, \ell_1), \Im\tilde{C}^*_T(r, \ell_2)) \right) | = o_p(1)$$

(ii) If in addition Assumption 5.2(B1) holds, then we have

$$|T \left( \text{cov}^*(\Re\hat{C}^*_T(r, \ell_1), \Re\hat{C}^*_T(r, \ell_2)) - \text{cov}^*(\Re\hat{C}^*_T(r, \ell_1), \Re\tilde{C}^*_T(r, \ell_2)) \right) | = o_p(1)$$

and

$$|T \left( \text{cov}^*(\Im\hat{C}^*_T(r, \ell_1), \Im\hat{C}^*_T(r, \ell_2)) - \text{cov}^*(\Im\hat{C}^*_T(r, \ell_1), \Im\tilde{C}^*_T(r, \ell_2)) \right) | = o_p(1).$$
Finally, by using the above, we obtain the following result.

**Theorem 5.2** Suppose Assumptions 5.2(B2) holds. Let the test statistic $T_{m,n,d}^*$ be defined as in (2.25), where the bootstrap variance is constructed using either $\hat{C}_T^*(r, \ell)$ or $\hat{C}_T^*(r, \ell)$ (if $\hat{C}_T^*(r, \ell)$ is used to construct the test statistic, then Assumption 5.2(B1) needs to hold too).

(i) Suppose Assumption 3.1 holds. Then we have

$$T_{m,n,d}^* \xrightarrow{P} \chi^2_{mnd(d+1)}.$$

(ii) Suppose Assumption 3.2 and $A(r, \ell) \neq 0$ for some $0 < r \leq m$ and $0 \leq \ell \leq n$ hold, then we have

$$T_{m,n,d}^* = O_p(Tp).$$

The above theorem shows that under fourth order stationarity the asymptotic distribution of $T_{m,n,d}^*$ (where we use the bootstrap variance as an estimator of $W_n$) is asymptotically equivalent to the test statistic as if $W_n$ were known. We observe that the mean length of the bootstrap block $1/p$ does not play a role in the asymptotic distribution under stationarity. This is in sharp contrast to the locally stationary case. If we did not use a bootstrap scheme to estimate $W_n^{-1/2}$ (i.e. we were to use $W_n = W_n^{(1)}$, which is the variance in the case of Gaussianity), then under local stationarity $T_{m,n,d} = O_p(T)$. However, by using the bootstrap scheme we incur a slight loss in power since $T_{m,n,d}^* = O_p(Tp)$.

6 Practical Issues

In this section, we consider the implementation issues related to the test statistic. We will be considering both the test statistic $T_{m,n,d}^*$, where we use the stationary bootstrap to estimate the variance, and compare it to the test statistic $T_{m,n,d,G}$ (defined in (2.21)) that is constructed as if the observations are Gaussian.

6.1 Selection of the tuning parameters

We recall from the definition of the test statistic that there are four different tuning parameters that need to be selected in order to construct the test statistic, to recap these are $b$ the bandwidth for spectral density matrix estimation, $m$ the number of DFT covariances $\hat{C}_T(r, \ell)$ (where $r = 1, \ldots, m$), $n$ the number of DFT covariances $\hat{C}_T(r, \ell)$ (where $\ell = 0, \ldots, n - 1$) and $p$ which determines the average block length (which is $p^{-1}$) in the bootstrap scheme. For the simulations below and the real data example, we use $n = 1$. This is because (a) in most situations it is likely that the nonstationarity is ‘seen’ in $\hat{C}_T(r, 0)$ and (b) we have shown that under the alternative of local stationarity $\hat{C}_T(r, \ell) \xrightarrow{P} A(r, \ell)$, where for $\ell \neq 0$ or $r \neq 0$ $A(r, \ell) = O(|\ell|^{-2}|r|^{-1})$, thus a large $n$ can result in a loss of power. However, we do recommend that a
plot of $\hat{C}_T(r, \ell)$ (or a standardized $\hat{C}_T(r, \ell)$) is made against $r$ and $\ell$ (similar to Figures 1–3) to see if there are any large coefficients which may be statistically significant. We now discuss how to select $b, m$ and $p$. These procedures will be used in the simulations below.

**Choice of the bandwidth $b$**

To estimate the spectral density matrix we need to select the bandwidth $b$. We use the cross-validation criterion, suggested in Beltrao and Bloomfield (1987) (see also Robinson (1991)).

**Choice of the number of lags $m$**

We select $m$ by adapting the data driven rule suggested by Escanciano and Lobato (2009) (who propose a method for selecting the number of lags in a Portmanteau test for testing uncorrelatedness of a time series). We summarize their procedure and then discuss how we use it to select $m$ in our test for stationarity. For univariate time series $\{X_t\}$, Escanciano and Lobato (2009) suggest selecting the number of lags in a Portmanteau test using the criterion

$$\hat{m}_P = \min\{m : 1 \leq m \leq D : L_m \geq L_h, h = 1, 2, \ldots, D\},$$

where $L_m = Q_m - \pi(m, T, q)$, $Q_m = T \sum_{j=1}^{m} |\hat{R}(j)\hat{R}(0)|^2$, $D$ is a fixed upper bound and $\pi(m, T, q)$ is a penalty term that takes the form

$$\pi(m, T, q) = \begin{cases} 
  m \log(T), & \max_{1 \leq k \leq D} \sqrt{T}|\hat{R}(k)/\hat{R}(0)| \leq \sqrt{q \log(T)} \ 
  2m, & \max_{1 \leq k \leq D} \sqrt{T}|\hat{R}(k)/\hat{R}(0)| > \sqrt{q \log(T)} 
\end{cases},$$

where $\hat{R}(k) = \frac{1}{T} \sum_{j=1}^{T} (X_j - \bar{X})(X_{j+k} - X)$. We now propose to adapt this rule to select $m$. More precisely, depending on whether we use $T_{m,1,d}$ or $T_{m,1,d,G}$ we define the sequences of bootstrap DFT covariances $\{\hat{\gamma}^*(r), r \in \mathbb{N}\}$ and non-bootstrap DFT covariances $\{\hat{\gamma}(r), r \in \mathbb{N}\}$, where

$$\hat{\gamma}^*(r) = \frac{1}{d(d+1)/2} \sum_{j=1}^{d(d+1)/2} \left\{ (\hat{W}_1^*(r))^{-1/2} \hat{R}\hat{K}_1(r)_j + (\hat{W}_1^*(r))^{-1/2} \hat{K}_1(r)_j \right\}$$

and $\hat{\gamma}(r)$ is defined similarly with $\hat{W}^*(r) = (\hat{W}^*(r))_{1,1}$ (defined in Step 6 of the bootstrap scheme) replaced by $W_0^{(1)}$ as in (2.21). We select $m$ by using

$$\hat{m} = \min\{m : 1 \leq m \leq D : L_m \geq L_h, h = 1, 2, \ldots, D\},$$

where $L_m = T_{m,1,d}^* - \pi^*(m, T, q)$ (or $T_{m,1,d,G}^* - \pi(m, T, q)$ if Gaussianity is assumed) and

$$\pi^*(m, T, q) = \begin{cases} 
  m \log(T), & \max_{1 \leq r \leq D} \sqrt{T}|\hat{\gamma}^*(r)| \leq \sqrt{q \log(T)}, 
  2m, & \max_{1 \leq r \leq D} \sqrt{T}|\hat{\gamma}^*(r)| > \sqrt{q \log(T)}.
\end{cases}$$

and $\pi(m, T, q)$ is defined similarly but using $\hat{\gamma}(r)$ instead of $\hat{\gamma}^*(r)$. 31
Choice of the average block size $1/p$

For the bootstrap test, the tuning parameter $1/p$ is chosen by adapting the rule suggested by Politis and White (2004) (and later corrected in Patton, Politis, and White (2009)) that was originally proposed in order to estimate the finite sample distribution of the univariate sample mean (using the stationary bootstrap). More precisely, to bootstrap the sample mean for dependent univariate time series $\{X_t\}$, they suggest to select the tuning parameter for the stationary bootstrap as

$$\frac{1}{p} = \left( \frac{\hat{G}^2}{\hat{g}^2(0)} \right)^{1/3} T^{1/3},$$

where $\hat{G} = \sum_{k=-M}^{M} \lambda(k/M) |k| \hat{R}(k)$, $\hat{g}(0) = \sum_{k=-M}^{M} \lambda(k/M) \hat{R}(k)$, $\hat{R}(k)$ defined above and

$$\lambda(t) = \begin{cases} 
1, & |t| \in [0, 1/2] \\
2(1 - |t|), & |t| \in [1/2, 1] \\
0, & \text{otherwise}
\end{cases}$$

is a trapezoidal shape symmetric flat-top taper. We have to adapt the rule (6.1) in two ways for our purposes. First, the theory established in Section 5 requires $Tp^4 \to \infty$ for the stationary bootstrap to be consistent. Hence, we suggest to use the same (estimated) constant as in (6.1), but we multiply it with $T^{1/5}$ instead of $T^{1/3}$ to meet these requirements. Second, as (6.1) is tailor-made for univariate data, we propose to apply it separately to all components of multivariate data and to define $1/p$ as the average value. We mention that proper selection of a $p$ (and in general the block length in any bootstrap procedure) is an extremely difficult problem and requires further investigation (see, for example, Paparoditis and Politis (2004) and Parker et al. (2006)).

6.2 Simulations

We now illustrate the performance of the test for stationarity of a multivariate time series through simulations. We will compare the test statistics $T_{m,n,d}^*$ and $T_{m,n,d;G}$, which are defined in (2.25) and (2.21), respectively. In the following, we refer to $T_{m,n,d}^*$ and $T_{m,n,d;G}$ as the bootstrap and the non-bootstrap test, respectively. Observe that the non-bootstrap test is asymptotically a test of level $\alpha$ only in the case that the fourth order cumulants are zero (which includes the Gaussian case). We reject the null of stationarity at the nominal level $\alpha \in (0, 1)$ if

$$T_{m,n,d}^* > \chi_{mnd(d+1)}^2(1 - \alpha) \quad \text{and} \quad T_{m,n,d;G} > \chi_{mnd(d+1)}^2(1 - \alpha).$$

(6.2)
6.2.1 Simulation setup

In the simulations below, we consider several stationary and nonstationary bivariate \( (d = 2) \) time series models. For each model we have generated \( M = 400 \) replications of the bivariate time series \( (X_t = (X_{t,1}, X_{t,2})', t = 1, \ldots, T) \) with sample size \( T = 500 \). As described above, the bandwidth \( b \) for estimating the spectral density matrices is chosen by cross-validation. To select \( m \), we set \( q = 2.4 \) (as recommended in Escanciano and Lobato (2009)) and \( D = 10 \). To compute the quantities \( \hat{G} \) and \( \hat{g}(0) \) for the selection procedure of \( 1/p \) (see (6.1)), we set \( M = 1/b \). Further, we have used \( N = 400 \) bootstrap replications for each time series.

6.2.2 Models under the null

To investigate the behavior of the tests under the null of (second order) stationarity of the process \( \{X_t\} \), we consider realizations from two vector autoregressive models (VAR), two GARCH-type models and one Markov switching model. Throughout this section, let

\[
A = \begin{pmatrix} 0.6 & 0.2 \\ 0 & 0.3 \end{pmatrix} \quad \text{and} \quad \Sigma = \begin{pmatrix} 1 & 0.3 \\ 0.3 & 1 \end{pmatrix}.
\]

To cover linear time series, we consider data \( X_1, \ldots, X_T \) from the bivariate VAR(1) models

\[
A X_{t-1} + \xi_t,
\]

(6.4)

where \( \{\xi_t, t \in \mathbb{Z}\} \) is a bivariate i.i.d. white noise process. For Model S(I), let \( \xi_t \sim \mathcal{N}(0, \Sigma) \). For Model S(II), the first component of \( \{\xi_t, t \in \mathbb{Z}\} \) consists of i.i.d. uniformly distributed random variables, \( \varepsilon_{t,1} \sim \mathcal{U}(-\sqrt{3}, \sqrt{3}) \) and the second component \( \{\varepsilon_{t,2}\} \) of \( t \)-distributed random variables with 5 degrees of freedom that are suitably multiplied such that \( E(\varepsilon_{t,1}\varepsilon_{t,1}') = \Sigma \) holds. Observe that the excess kurtosis for these two innovation distributions are \(-6/5\) and \(6\), respectively.

The two GARCH-type Models S(III) and S(IV) are based on two independent, but identically distributed univariate GARCH(1,1) processes \( \{Y_{t,i}, t \in \mathbb{Z}\}, i = 1, 2 \), each with

\[
Y_{t,i} = \sigma_{t,i} \varepsilon_{t,i}, \quad \sigma_{t,i}^2 = 0.01 + 0.3Y_{t-1,i}^2 + 0.5\sigma_{t-1,i}^2,
\]

(6.5)

where \( \{\varepsilon_{t,i}, t \in \mathbb{Z}\}, i = 1, 2 \), are two independent i.i.d. standard normal white noise processes. Now, Model S(III) and S(IV) correspond to the processes \( \{X_t = \Sigma^{1/2}(Y_{t,1}, Y_{t,2})', t \in \mathbb{Z}\} \) and \( \{X_t = \Sigma^{1/2}((|Y_{t,1}|, |Y_{t,2}|)' - E((|Y_{t,1}|, |Y_{t,2}|)'), t \in \mathbb{Z}\} \), respectively (the first is the GARCH process, the second are the (centered) absolute values of the GARCH). Both these models are nonlinear and their fourth order cumulant structure is complex. Finally, we consider a VAR(1) regime switching model

\[
A X_{t-1} + \xi_t, \quad s_t = 0,
\]

\[
\xi_t, \quad s_t = 1,
\]

(6.6)
where \( \{s_t\} \) is a (hidden) Markov process with two regimes such that \( P(s_t \in \{0, 1\}) = 1 \) and \( P(s_t = s_{t-1}) = 0.95 \) and \( \{e_t, t \in \mathbb{Z}\} \) is a bivariate i.i.d. white noise process with \( e_t \sim \mathcal{N}(0, \Sigma) \).

Realizations of stationary Models S(I)–S(V) are shown in Figure 1 together with the corresponding DFT covariances \( T|\hat{C}_{11}(r, 0)|^2, T|\sqrt{2}\hat{C}_{21}(r, 0)|^2 \) and \( T|\hat{C}_{22}(r, 0)|^2, r = 1, \ldots, 10 \). The performance under the null of both tests \( T_{m,n,d}^* \) and \( T_{m,n,d;G} \) are reported in Table 1.

**Discussion of the simulations under the null**

For the stationary Models S(I)–S(V), the DFT covariances for lags \( r = 1, \ldots, 10 \) are shown in Figure 1. These plots illustrate their different behaviors under Gaussianity and non-Gaussianity. In particular, for the Gaussian Model S(I), it can be seen that the DFT covariances seem to fit to the theoretical \( \chi^2 \)-distribution. Contrary to that, for the corresponding non-Gaussian Model S(II), they appear to have larger variances. Hence, in this case, it is necessary to use the bootstrap to estimate the proper variance in order to standardize the DFT covariances before constructing the test statistic. For the non-linear GARCH-type Models S(III) and S(IV), this effect becomes even more apparent and here it is absolutely necessary to use the bootstrap to correct for the larger variance (due to the fourth order cumulants). For the Markov switching Model S(V), this effect is also present, but not that strong in comparison to the GARCH-type models S(III) and S(IV).

In Table 1, the performance in terms of actual size of the bootstrap test \( T_{m,n,d}^* \) and of the non-bootstrap test \( T_{m,n,d;G} \) are presented. For Model S(I), where the underlying time series is Gaussian, the test \( T_{m,n,d;G} \) performs superior to \( T_{m,n,d}^* \), which tends to be conservative and underrejects the null. However, if we leave the Gaussian world, the corresponding non-Gaussian Model S(II) shows a different picture. In this case, the non-bootstrap test \( T_{m,n,d;G} \) clearly overrejects the null significantly, where the bootstrap test \( T_{m,n,d}^* \) still remains conservative, but holds the prescribed level. For the GARCH-type Model S(III), both tests do not succeed in attaining the nominal level (overrejecting the null). However, there are two important factors which explain this. On the one hand, the non-bootstrap test \( T_{m,n,d;G} \) just does not take the fourth order structure contained in the process dynamics into account, which leads to a test that significantly overrejects the null, because in this case the DFT covariances are not properly standardized. On the other hand, the bootstrap procedure used for constructing \( T_{m,n,d}^* \) relies to a large extent on the choice of the tuning parameter \( p \), which controls the average block length of the stationary bootstrap and, hence, for the dependence captured by the bootstrap samples. However, the data-driven rule (defined in Section 6.1) for selecting \( 1/p \) is based on the correlation structure of the data and the GARCH process is uncorrelated. This leads the rule to selecting a very small \( 1/p \) (typically it chooses a mean block length of 1 or 2). With
such a small block length the fourth order cumulant in the variance cannot be estimated properly, indeed it underestimates it. For Model S(IV), we take the absolute values of GARCH processes, such that serial correlation becomes visible in the data. Hence, the data-driven rule selects a larger tuning parameter $1/p$ in comparison to Model S(III). Therefore, a relatively accurate estimate of the (large) variance of the DFT covariance is obtained, leading to the bootstrap test $T_{m,n,d}^*$ attaining an accurate nominal level. However, as expected, the non-bootstrap test $T_{m,n,d;G}$ fails to attain the nominal level (since the kurtosis of the GARCH model is large, thus this model is highly ‘non-Gaussian’). Finally, the bootstrap test performs well for the VAR(1) switching Model S(V), whereas the non-bootstrap test $T_{m,n,d;G}$ tends to slightly overreject the null.

6.2.3 Models under the alternative

To illustrate the behavior of the tests under the alternative of (second order) nonstationarity, we consider realizations from three models fulfilling different types of nonstationary behavior. As we focus on locally stationary alternatives, where nonstationarity is caused by smoothly changing dynamics, we consider first the time-varying VAR(1) model (tvVAR(1))

$$X_t = AX_{t-1} + \sigma \left( \frac{t}{T} \right) \varepsilon_t, \quad t = 1, \ldots, T,$$

(6.7)

where $\sigma(u) = 2\sin(2\pi u)$ and $A$ as defined in (6.3). Further, we include a second tvVAR(1) model, where the dynamics are not present in the innovation variance, but in the coefficient matrix. More precisely, we consider the tvVAR(1) model

$$X_t = A \left( \frac{t}{T} \right) X_{t-1} + \varepsilon_t, \quad t = 1, \ldots, T,$$

(6.8)

where $A(u) = \sin(2\pi u) A$. Finally, we consider the unit root case (noting that several authors have considered tests for stochastic trend, including Pelagatti and Sen (2013)), though this case has not been treated in our asymptotic theory. In particular, we consider observations from a bivariate random walk

$$X_t = X_{t-1} + \varepsilon_t, \quad t = 1, \ldots, T, \quad X_0 = 0.$$

(6.9)

In all Models NS(I)–NS(III) above, $\{\varepsilon_t, t \in \mathbb{Z}\}$ is a bivariate i.i.d. white noise process with $\varepsilon_t \sim \mathcal{N}(0, \Sigma)$ and $\Sigma$ as defined in (6.3).

In Figure 2 we show realizations of nonstationary Models NS(I)–NS(III) together with DFT covariances $T|\hat{C}_{11}(r,0)|^2$, $T|\sqrt{2}\hat{C}_{21}(r,0)|^2$ and $T|\hat{C}_{22}(r,0)|^2$, $r = 1, \ldots, 10$ to illustrate how the type of nonstationarity is encoded. The performance under nonstationarity of both tests $T_{m,n,d}^*$ and $T_{m,n,d;G}$ are reported in Table 2 for sample size $T = 500$. 

35
Discussion of the simulations under the alternative

The DFT covariances for the nonstationary Models NS(I)–NS(III) as displayed in Figures 2 illustrate how and why the proposed testing procedure is able to detect nonstationarity in the data. For both locally stationary Models NS(I) and NS(II), it can be seen that the nonstationarity is encoded mainly in the DFT covariances at lag two, where the peak is significantly more pronounced for Model NS(I) in comparison to Model NS(II). Contrary to that behavior, for the random walk Model NS(III), the DFT covariances are large for all lags.

In Table 2 we report the results for the tests, where the power for the bootstrap test \( T^*_m,n,d \) and for the non-bootstrap test \( T_{m,n,d;G} \) are given. It can be seen that both tests have good power properties for the tvVAR(1) Model NS(I), where the non-bootstrap test \( T_{m,n,d;G} \) is slightly superior to the bootstrap test \( T^*_m,n,d \). Here, it is interesting to note that the time-varying spectral density for Model NS(I) is 
\[
f(u, \omega) = \frac{1}{2}(1 - \cos(4\pi u))f_Y(\omega),
\]
where \( f_Y(\omega) \) is the spectral density matrix corresponding to the stationary time series \( Y_t = AY_{t-1} + 2\varepsilon_t \). Comparing this to the Fourier coefficients \( A(r, 0) \) (defined in (3.9)), we see that for this example \( A(2, 0) \neq 0 \) whereas \( A(r, 0) = 0 \) for \( r \neq 2, r > 0 \) (which can be seen in Figure 2). In contrast, neither the bootstrap nor non-bootstrap test performs well for Model NS(II) (here the rejection rate is less than 40% even in the Gaussian case when using the 10% level). However, from Figure 2 of the DFT covariance we do see a clear peak at lag two, but this peak is substantially smaller than the corresponding peak in Model NS(I). A plausible explanation for the poor performance of the test in this case is that even when \( m = 2 \) the test we use a chi-square with \( d(d + 1) \times m = 2 \times 3 \times 2 = 12 \) degrees of freedom which pushes the rejection region to the right, thus making it extremely difficult to reject the null unless the sample size or \( A(r, \ell) \) are extremely large. Since a visual inspection of the covariance shows clear signs of nonstationarity, this suggests that further work is needed in selecting which DFT covariances should be used in the testing procedure (especially in the multivariate setting where using a component wise scheme may be useful).

Finally, both tests have good power properties for the random walk Model NS(III). As the theory suggests (see Theorem 5.2), for all three nonstationary models the non-bootstrap procedure has better power than the bootstrap procedure.

6.3 Real data application

We now consider a real data example, in particular the log-returns over \( T = 513 \) trading days of the FTSE 100 and the DAX 30 stock price indexes between January 1st 2011 and December 31st, 2012. A plot of both indexes is given in Figure 3. Typically, a stationary GARCH-type model is fitted to the log returns
of stock index data. Therefore, in this section we investigate whether it is reasonable to assume that this time series is stationary. We first make a plot of the DFT covariances \( T|\hat{C}_{11}(r, 0)|^2 \), \( T|\sqrt{2}\hat{C}_{21}(r, 0)|^2 \) and \( T|\hat{C}_{22}(r, 0)|^2 \) (see Figure 3). We observe that most of the covariances are above the 5% level of a \( \chi^2 \) distribution (however we note that \( \hat{C}_T(r, 0) \) has not been standardized). We then apply the bootstrap test \( T_{m,n,d}^* \) and the non-bootstrap test \( T_{m,n,d;G} \) to the raw log-returns. In this case, both tests reject the null of second-order stationarity at the \( \alpha = 1\% \) level. However, we recall from the simulation study in Section 6.2 (Models S(III) and S(IV)) that the tests tends to falsely reject the null for a GARCH model. Therefore, to make sure that the small p-value is not a mistake in the testing procedure, we consider the absolute values of log returns. A plot of the corresponding DFT covariances \( T|\hat{C}_{11}(r, 0)|^2 \), \( T|\sqrt{2}\hat{C}_{21}(r, 0)|^2 \) and \( T|\hat{C}_{22}(r, 0)|^2 \) is given in Figure 3. Applying the non-bootstrap test gives a p-value of less than 0.1\% and the bootstrap test gives a p-value of 3.9\%. Therefore, an analysis of both the log-returns and the absolute log-returns of the FTSE 100 and DAX 30 stock price indexes strongly suggest that this time series is nonstationary and fitting a stationary model to this data may not be appropriate.

A Proofs

A.1 Preliminaries

In order to derive its properties, we use that \( \widetilde{c}_{j_1,j_2}(r, \ell) \) can be written as

\[
\widetilde{c}_{j_1,j_2}(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} L_{j_1,s}(\omega_k) \overline{L}_{j_2,s}(\omega_{k+r}) \exp(i\ell \omega_k)
\]

\[
= \frac{1}{T} \sum_{k=1}^{T} \sum_{s_1,s_2=1}^{d} L_{j_1,s_1}(\omega_k) J_{T,s_1}(\omega_k) L_{j_2,s_2}(\omega_k) \exp(i\ell \omega_k),
\]

where \( L_{j,s}(\omega_k) \) is entry \((j,s)\) of \( L(\omega_k) \) and \( L_{j,s}(\omega_k) \) denotes its \( j \)th row.

We will assume throughout the appendix that the lag window satisfies Assumption 2.1 and we will use the notation \( \tilde{g} \) for \( g \) and \( \tilde{f} \) for \( f \). Let \( J_{T,s}(\omega_k) \) be the lower-triangular matrix \( J_{T,s}(\omega_k) = L_{j_2,s}(\omega_k) L_{j_1,s}(\omega_k) \exp(i\ell \omega_k) \), and define the lower-triangular matrix \( \overline{L}_{j_2,s}(\omega_{k+r}) \) of \( L(\omega_{k+r}) \) such that \( \overline{L}_{j_2,s}(\omega_{k+r}) = L_{j_2,s}(\omega_{k+r}) \). Furthermore, let us suppose that \( G \) is a positive definite matrix, \( \overline{G} = \text{vec}(G) \) and define the lower-triangular matrix \( L(\overline{G}) \) such that \( L(\overline{G}) L(\overline{G})' = I \) (hence \( L(\overline{G}) \) is the inverse of the Cholesky decomposition of \( G \)). Let \( L_{js}(\overline{G}) \) denote the \((j,s)\)th element of the Cholesky matrix \( L(\overline{G}) \). Let \( \nabla L_{js}(\overline{G}) = (\frac{\partial L_{js}(\overline{G})}{\partial G_{11}}, \ldots, \frac{\partial L_{js}(\overline{G})}{\partial G_{dd}})' \) and \( \nabla^n L_{js}(\overline{G}) \) denote the vector of all partial \( n \)th order derivatives wrt \( G \). Furthermore, to reduce notation let \( \tilde{L}_{js}(\omega) = \frac{\partial \tilde{g}(\omega)}{\partial G_{11}} \) and \( \tilde{L}_{js}(\omega) = \frac{\partial \tilde{f}(\omega)}{\partial G_{11}} \).

In the stationary case, let \( \kappa(h) = \text{cov}(X_{h}, X_{h}) \) and in the locally stationary case \( \kappa(u; h) \) is defined in Assumption 3.2.

Before proving Theorems 3.1 and 3.5 we first state some preliminary results.

**Lemma A.1**

(i) Let \( G = (g_{kl}) \) be a positive definite \((d \times d)\) matrix. Then, for all \( 1 \leq j, s \leq d \) and all \( r \in \mathbb{N}_0 \), there exists an \( \epsilon > 0 \) and a set \( \mathcal{M}_\epsilon = \{ M : \| G - M \|_1 < \epsilon \text{ and } M \text{ is positive definite} \} \) such that

\[
\sup_{M \in \mathcal{M}_\epsilon} \| \nabla^r L_{js}(M) \|_1 < \infty.
\]

(ii) Let \( G(\omega) \) be a \((d \times d)\) uniformly continuous spectral density matrix function with \( \inf_{\omega} \lambda_{\min}(G(\omega)) > 0 \). Then, for all \( 1 \leq j, s \leq d \) and all \( r \in \mathbb{N}_0 \), there exists an \( \epsilon > 0 \) and a set \( \mathcal{M}_\epsilon,\omega = \{ M(\cdot) : |G(\omega) - M(\omega)|_1 < \epsilon \text{ and } M(\omega) \text{ is positive definite for all } \omega \} \) such that

\[
\sup_{\omega} \sup_{M(\cdot) \in \mathcal{M}_\epsilon,\omega} \| \nabla^r L_{js}(M(\omega)) \|_1 < \infty.
\]
PROOF. (i) For a positive definite matrix $M$, let $M = BB^T$, where $B$ denotes the lower-triangular Cholesky decomposition of $M$ and we set $C = B^{-1}$. Further, let $Ψ$ and $Φ$ be defined by $B = Ψ(G)$ and $C = Φ(B)$, i.e. $Ψ$ maps a positive definite matrix to its Cholesky matrix and $Φ$ maps an invertible matrix to its inverse. Further suppose $λ_{min}(G) =: η$ and $λ_{max}(G) =: η$ for some positive constants $η ≤ η$ and let $ε > 0$ be sufficiently small such that $0 < η - ε ≤ λ_{min}(M) ≤ λ_{max}(M) ≤ η + δ < ∞$ for all $M ∈ M_ε$ and some $δ > 0$. The latter is possible because the eigenvalues are continuous functions in the matrix entries.

Now, due to

\[ L_{kl}(M) = c_{kl} = Φ_{kl}(B) = Φ_{kl}(Ψ(M)) \]

and the chain rule, it suffices to show that (a) all entries of $Ψ$ have partial derivatives of all orders on the set of all positive definite matrices $M = (m_{kl})$ with $0 < η - ε ≤ λ_{min}(M) ≤ λ_{max}(M) ≤ η + δ < ∞$ for some $δ > 0$ and (b) all entries of $Φ$ have partial derivatives of all orders on the set $L_ε$ of all lower triangular matrices with diagonal elements lying in $[ζ, ζ]$ for some suitable $0 < ζ ≤ ζ < ∞$ depending on $δ$ above such that $Ψ(M_ε) ⊂ L_ε$. In particular, the diagonal entries (the eigenvalues) of $B$ are bounded from above and also away from zero. As there are no explicit formulas for $B = Ψ(M)$ and $C = Φ(B)$, their entries have to be calculated recursively by

\[
 b_{kl} = \begin{cases} 
 \frac{1}{b_{kk}}(m_{kk} - \sum_{j=1}^{l-1} b_{kj}b_{lj}), & k > l \\
 m_{kk} - \sum_{j=1}^{k} b_{kj}b_{kj})^{1/2}, & k = l \\
 0, & k < l 
\end{cases}
\]

and

\[
 c_{kl} = \begin{cases} 
 -\frac{1}{b_{kk}} \sum_{j=1}^{k-1} b_{kj}c_{lj}, & k > l \\
 \frac{1}{b_{kk}}, & k = l \\
 0, & k < l 
\end{cases}
\]

where the recursion is done row by row (top first), starting from the left hand side of each row to the right.

To prove (a), we order the non-zero entries of $B$ row-wise and get for the first entry $Ψ_{11}(M) = b_{11} = \sqrt{m_{11}}$, which is arbitrarily often partially differentiable as $m_{11} > 0$ is bounded away from zero on $M_ε$. Now we proceed recursively by induction. Suppose that $b_{kl} = Ψ_{kl}(M)$ is arbitrarily often partially differentiable for the first $p$ non-zero elements of $B$ on $M_ε$. The $(p+1)$th non-zero element is $b_{st}$, say. For $s = t$, we get

\[
 Ψ_{ss}(M) = b_{ss} = \left( m_{ss} - \sum_{j=1}^{s-1} b_{sj}b_{sj} \right)^{1/2} = \left( m_{ss} - \sum_{j=1}^{s-1} Ψ_{sj}(M)Ψ_{sj}(M) \right)^{1/2},
\]

and for $s > t$, we have

\[
 Ψ_{st}(M) = b_{st} = \frac{1}{Ψ_{tt}(M)} \left( m_{st} - \sum_{j=1}^{t-1} Ψ_{sj}(M)Ψ_{tj}(M) \right),
\]

such that all partial derivatives of $Ψ_{st}(M)$ exist on $M_ε$ as $Ψ_{st}(M)$ is composed of such functions and due to $m_{ss} - \sum_{j=1}^{s-1} b_{sj}b_{sj}$ and $Ψ_{tt}(M)$ uniformly bounded away from zero on $M_ε$. This proves part (a). To
prove part (b), we get immediately that \( \Phi_{kk}(B) = c_{kk} \) has all partial derivatives on \( L_\varepsilon \) as \( b_{kk} \) is bounded way from zero for all \( k \). Now, we order the non-zero off-diagonal elements of \( C \) row-wise and for the first such entry we get \( \Phi_{21}(B) = c_{21} = -c_{21}/c_{22} \) which is arbitrarily often partially differentiable again as \( b_{22} \) is bounded way from zero. Now we proceed again recursively by induction. Suppose that \( c_{kl} = \Phi_{kl}(B) \) is arbitrarily often partially differentiable for the first \( p \) non-zero off-diagonal elements of \( C \).

The \((p+1)\)th non-zero element equals \( c_{st} \), say, and we have

\[
\Phi_{st}(B) = c_{st} - \frac{1}{b_{ss}} \sum_{j=l}^{s-1} b_{sj} c_{jt} = -\frac{1}{b_{ss}} \sum_{j=l}^{s-1} b_{sj} \Phi_{jt}(B)
\]

and all partial derivatives of \( \Phi_{st}(B) \) exist on \( L_\varepsilon \) as \( \Phi_{st}(B) \) is composed of such functions and due to \( b_{ss} > 0 \) uniformly bounded away from zero on \( L_\varepsilon \). This proves part (b) and concludes part (i) of this proof.

(ii) As in part (i), we get with an analogue notation (depending on \( \omega \)) the relation

\[
L_{kl}(M(\omega)) = c_{kl}(\omega) = \Phi_{kl}(B(\omega)) = \Phi_{kl}(\Phi(M(\omega)))
\]

and again by the chain rule, it suffices to show that (a) all entries of \( \Phi \) have partial derivatives of all orders on the set of all uniformly positive definite matrix functions \( M(\cdot) \) with \( 0 < \frac{1}{2} - \delta \leq \inf_{\omega} \lambda_{\min}(M(\omega)) \leq \sup_{\omega} \lambda_{\max}(M(\omega)) \leq \frac{1}{2} + \delta \) and (b) all entries of \( \Phi \) have partial derivatives of all orders on the set \( L_{\varepsilon,\omega} \) of all lower triangular matrix functions with diagonal elements lying in \([\underline{\zeta}, \overline{\zeta}]\) for some suitable \( 0 < \underline{\zeta} \leq \overline{\zeta} < \infty \) depending on \( \delta \) such that \( \Phi(M_{\varepsilon,\omega}) \subset L_{\varepsilon,\omega} \). The rest of the proof of part (ii) is analogue to the proof of (i) above.

Lemma A.2 Suppose that \( \{X_t\} \) is a second order stationary or locally stationary time series (which satisfies Assumption 3.2(L2)) where for \( h \neq 0 \) either the covariance or local covariance satisfies \( |\kappa(h)|_1 \leq C|h|^{-(2+\varepsilon)} \) or \( |\kappa(u;h)|_1 \leq C|h|^{-(2+\varepsilon)} \) for some constant \( C < \infty \), respectively, and further, we assume

\[
\sup_t \sum_{h_1, h_2, h_3} |\text{cum}(X_{t,j_1}, X_{t+h_1,j_2}, X_{t+h_2,j_1}, X_{t+h_3,j_2})| < \infty.
\]

Let \( \hat{f}_T(p) \) be defined as in (2.6). Then,

(a) \( \text{var}(\hat{f}_T(p)) = O((bT)^{-1}) \) and \( \sup_\omega |E(\hat{f}_T(p)) - f(\omega)| = O(b + (bT)^{-1}) \).

(b) If in addition, we have

\[
\sup_t \sum_{h_1, \ldots, h_s} |\text{cum}(X_{t,j_1}, X_{t+h_1,j_2}, \ldots, X_{t+h_s,j_s})| < \infty \text{ for } s = 1, \ldots, 7,
\]

then

\[
\|\hat{f}_T(p) - E(\hat{f}_T(p))\|_4 = O(\frac{1}{(bT)^{1/2}}).\]

(c) If in addition, \( b^2 T \to \infty \) then we have

(i) \( \sup_\omega |\hat{f}_T(p) - f(\omega)|_1 \xrightarrow{P} 0 \),

(ii) Further, if \( f(\omega) \) is nonsingular on \([0, 2\pi] \), then we have \( \sup_\omega |L_{js}(\hat{f}(\omega)) - L_{js}(f(\omega))| \xrightarrow{P} 0 \) as \( T \to \infty \) for all \( 1 \leq j, s \leq d \).
PROOF. To simplify the proof most parts will be proven for the univariate case - the proof of the multivariate case is identical. By making a simple expansions it is straightforward to show that

\[
\hat{f}_T(\omega) = \frac{1}{2\pi T} \sum_{t, \tau = 1}^{T} \lambda_b(t - \tau)(X_t - \mu)(X_\tau - \mu) \exp(-i(t - \tau)\omega) + R_T(\omega),
\]  
(A.2)

where

\[
R_T(\omega) = \frac{\mu - \mathbb{X}}{2\pi T} \sum_{t, \tau = 1}^{T} \lambda_b(t - \tau)e^{-i(t-\tau)\omega} \left[(X_t - \mu) + (X_\tau - \mu) - (\mu - \mathbb{X})\right]
\]

\[
= \frac{(\mu - \mathbb{X})^2}{2\pi} \sum_{h = -(T-1)}^{T-1} \frac{T - |h|}{T} \lambda_b(h)e^{-ih\omega}
\]

\[+ \frac{\mu - \mathbb{X}}{2\pi} \sum_{h = -(T-1)}^{T-1} \lambda_b(h)(e^{-ih\omega} + e^{ih\omega}) \left[\frac{1}{T} \min(T - T - h) \sum_{t = \max(1, 1 - h)}^{\min(T - T - h)} (X_t - \mu)\right]
\]

Under absolute summability of the second and fourth order cumulants and Assumption 2.1 we have

\[\mathbb{E}\sup_{\omega} R_T(\omega) = O(\frac{1}{T^2} + \frac{1}{T^{1/2}h^{1/2}})\]

(similar bounds can also be obtained for higher moments if the corresponding cumulants are absolutely summable). We will show later on in the proof that \(R_T(\omega)\) is dominated by the first term in on the right hand side of (A.2). Therefore, to simplify notation, as the mean estimator is insignificant, for the remainder of the proof we will assume that the mean is known and it is \(\mathbb{E}(X_t) = 0\). Consequently, the mean is not estimated and the spectral density estimator is

\[\hat{f}_T(\omega) = \frac{1}{2\pi T} \sum_{t, \tau = 1}^{T} \lambda_b(t - \tau)X_tX_\tau \exp(-i(t - \tau)\omega).
\]

To prove (a) we evaluate the variance of \(\hat{f}_T(\omega)\)

\[\text{var}(\hat{f}_T(\omega)) = \frac{1}{4\pi^2 T^2} \sum_{t_1, \tau_1 = 1}^{T} \sum_{t_2, \tau_2 = 1}^{T} \lambda_b(t_1 - \tau_1)\lambda_b(t_2 - \tau_2)\text{cov}(X_{t_1}X_{\tau_1}, X_{t_2}X_{\tau_2}) \exp(-i(t_1 - \tau_1 - t_2 + \tau_2)\omega).
\]

By using indecomposable partitions on the covariances in the sum to partition it into covariances and cumulants of \(X_t\) and under the absolute summable covariance and cumulant assumptions, we have that

\[\text{var}(\hat{f}_T(\omega)) = O(\frac{1}{T^2})\]

Next we obtain a bound for the bias. We do so, under the assumption of local stationarity, in particular the smooth assumptions in Assumptions 3.2(L2) (in the stationary case we do not require these assumptions). Taking expectations we have

\[\mathbb{E}(\hat{f}_T(\omega)) = \frac{1}{2\pi} \sum_{h = -(T-1)}^{T-1} \lambda_b(h) \exp(-ih\omega) \frac{1}{T} \sum_{t = \max(1, 1 - h)}^{\min(T - T - h)} \text{cov}(X_{t+h}, X_t)
\]

\[= \frac{1}{2\pi} \sum_{h = -(T-1)}^{T-1} \lambda_b(h) \exp(-ih\omega) \frac{1}{T} \sum_{t = \max(1, 1 - h)}^{\min(T - T - h)} \kappa \left(\frac{t}{T}; h\right) + R_1(\omega),
\]

(A.3)
where
\[ \sup \omega |R_1(\omega)| \leq \frac{1}{2\pi T} \sum_{t=1}^{T} \lambda_b(t - \tau) \left| \text{cov}(X_t, X_{\tau}) - \kappa \left( \frac{\tau}{T}; t - \tau \right) \right| = O \left( \frac{1}{T} \right) \hspace{1cm} \text{(by Assumption 3.2(L2))}. \]

Changing the inner sum in (A.3) with an integral gives
\[ \mathbb{E}(\hat{f}_T(\omega)) = \frac{1}{2\pi} \sum_{h=-\infty}^{\infty} \lambda_b(h) \exp(-i\omega) \kappa(h) + R_1(\omega) + R_2(\omega) \]
where \( \kappa(h) = \int_0^1 \kappa(u; h)du \) and
\[ \sup \omega |R_2(\omega)| \leq \frac{1}{2\pi} \sum_{h=-\infty}^{\infty} \lambda_b(h) \left( \frac{|h|}{T} \max_u |\kappa(u; h)| + \frac{1}{T} \sum_{t=1}^{T} \kappa \left( \frac{t}{T}; h \right) - \int_0^1 \kappa(u; h)du \right) = O \left( \frac{1}{bT} \right). \]

Finally, we take differences between \( \mathbb{E}(\hat{f}_T(\omega)) \) and \( f(\omega) \) which gives
\[ \mathbb{E}[\hat{f}_T(\omega)] - f(\omega) = \frac{1}{2\pi} \sum_{|h| \leq 1/b} (\lambda_b(h) - 1) \kappa(h) \exp(-i\omega) + \frac{1}{2\pi} \sum_{|h| > 1/b} \kappa(h) \exp(-i\omega) + R_1(\omega) + R_2(\omega). \]

To bound \( R_3(\omega) \), we use Assumption 2.1(K1) to give
\[ R_3(\omega) = \frac{1}{2\pi} \sum_{|h| \leq 1/b} (\lambda(hb) - 1) \kappa(h) \exp(-i\omega) = \frac{b}{2\pi} \sum_{|h| \leq 1/b} h \cdot \lambda'(x_{hb}) \kappa(h) \exp(-i\omega), \]
where \( x_{hb} \) lies between 0 and \( hb \). Therefore, we have \( \sup \omega |R_3(\omega)| = O(b) \). Altogether, this gives the bias \( O(b + \frac{1}{bT}) \) and we have proven (a).

To evaluate \( \mathbb{E}[\hat{f}_T(\omega) - \mathbb{E}(\hat{f}_T(\omega))]^4 \), we use the expansion
\[ \mathbb{E}[\hat{f}_T(\omega) - \mathbb{E}(\hat{f}_T(\omega))]^4 = 3 \text{var}(\hat{f}_T(\omega))^2 + \text{cum}_4(\hat{f}_T(\omega)). \]

The bound for \( \text{cum}_4(\hat{f}_T(\omega)) \) uses an identical method to the variance calculation in part (a). By using the cumulant summability assumption we have \( \text{cum}_4(\hat{f}_T(\omega)) = O \left( \frac{1}{bT} \right) \), this proves (b).

We now prove (ci). By the triangle inequality, we have
\[ \sup \omega |\hat{f}_T(\omega) - f(\omega)| \leq \sup \omega |\hat{f}_T(\omega) - \mathbb{E}(\hat{f}_T(\omega))| + \sup \omega |\mathbb{E}(\hat{f}_T(\omega)) - f(\omega)|. \]

Therefore, we only need to show that the first term of the above converges to zero. To prove \( \sup \omega |\hat{f}_T(\omega) - \mathbb{E}[\hat{f}_T(\omega)]| \overset{P}{\to} 0 \), we first show
\[ \mathbb{E} \left( \sup \omega |\hat{f}_T(\omega) - \mathbb{E}(\hat{f}_T(\omega))|^2 \right) \to 0 \hspace{1cm} \text{as} \hspace{1cm} T \to \infty. \]
and then we apply Chebyshev’s inequality. To bound $E(\sup_{\omega} | \hat{T}(\omega) - E(\hat{T}(\omega))|^2)$, we will use Theorem 3B, page 85, Parzen (1999). There it is shown that if $\{X(\omega); \omega \in [0, \pi]\}$ is a zero mean stochastic process, then

$$E\left( \sup_{0 \leq \omega \leq \pi} |X(\omega)|^2 \right) \leq \frac{1}{2} E|X(0)|^2 + \frac{1}{2} E|X(\pi)|^2 + \int_0^\pi \left[ \text{var}(X(\omega)) \text{var} \left( \frac{\partial X(\omega)}{\partial \omega} \right) \right]^{1/2} d\omega. \quad (A.4)$$

To apply the above lemma, let $X(\omega) = \hat{T}(\omega) - E[\hat{T}(\omega)]$ and the derivative of $\hat{T}(\omega)$ is

$$\frac{\partial \hat{T}(\omega)}{\partial \omega} = \frac{1}{2\pi T} \sum_{t, \tau = 1}^T -i(t-\tau)X_tX_\tau \lambda(\tau - \tau) \exp(-i(t-\tau)\omega).$$

By using the same arguments as those used in (a), we have $\text{var} \left( \frac{\partial \hat{T}(\omega)}{\partial \omega} \right) = O\left( \frac{1}{b^{3/2}T} \right)$. Therefore, by using (A.4), we have

$$E\left( \sup_{0 \leq \omega \leq \pi} | \hat{T}(\omega) - E[\hat{T}(\omega)] |^2 \right) \leq \frac{1}{2} \text{var}[\hat{T}(0)] + \frac{1}{2} \text{var}[\hat{T}(\pi)] + \int_0^\pi \left[ \text{var}(\hat{T}(\omega)) \text{var} \left( \frac{\partial \hat{T}(\omega)}{\partial \omega} \right) \right]^{1/2} d\omega = O \left( \frac{1}{b^{3/2}T} \right).$$

Thus, by using the above and Chebyshev’s inequality, for any $\varepsilon > 0$, we have

$$P \left( \sup_{\omega} | \hat{T}(\omega) - E[\hat{T}(\omega)] | > \varepsilon \right) \leq \frac{E\sup_{\omega} | \hat{T}(\omega) - E[\hat{T}(\omega)] |^2}{\varepsilon^2} = O \left( \frac{1}{Tb^{3/2}\varepsilon} \right) \to 0$$

as $Tb^{3/2} \to \infty$, $b \to 0$ and $T \to \infty$. This proves (ci).

To prove (cii), we return to the multivariate case. We recall that a sequence $\{X_T\}$ converges in probability to zero if and only if for every subsequence $\{T_k\}$ there exists a subsequence $\{T_{k_i}\}$ such that $X_{T_{k_i}} \to 0$ with probability one (see, for example, (Billingsley, 1995), Theorem 20.5). Now, the uniform convergence in probability result in (ci) implies that for every sequence $\{T_k\}$ there exists a subsequence $\{T_{k_i}\}$ such that $\sup_{\omega} | \hat{f}_{T_{k_i}}(\omega) - \bar{f}(\omega) | \overset{P}{\to} 0$ with probability one. Therefore, by applying the mean value theorem to $L_{j_s}$, we have

$$L_{j_s}(\hat{f}_{T_{k_i}}(\omega)) - L_{j_s}(\bar{f}(\omega)) = \nabla L_{j_s}(\hat{f}_{T_{k_i}}(\omega))(\hat{f}_{T_{k_i}}(\omega) - \bar{f}(\omega)), \quad \text{where } \hat{f}_{T_{k_i}}(\omega) = vec(\hat{f}_{T_{k_i}}(\omega)) \text{ with } \hat{f}_{T_{k_i}}(\omega) = \alpha_{T_{k_i}}(\omega) \hat{f}_{T_{k_i}}(\omega) + (1-\alpha_{T_{k_i}}(\omega)) \bar{f}(\omega).$$

Clearly, for $T_k$ large enough, $\hat{f}_{T_{k_i}}(\omega)$ is a positive definite matrix (since it is a weighted average of two positive definite matrices) and we have that $\hat{f}_{T_{k_i}}(\omega)$ is such that $\sup_{\omega} | \hat{f}_{T_{k_i}}(\omega) - \bar{f}(\omega) | < \varepsilon$ for all $T_{k_i} > T_k$. Thus, the conditions of Lemma A.1(ii) are satisfied and for large enough $T_k$ we have that

$$\sup_{\omega} | L_{j_s}(\hat{f}_{T_{k_i}}(\omega)) - L_{j_s}(\bar{f}(\omega)) | \leq \sup_{\omega} | \nabla L_{j_s}(\hat{f}_{T_{k_i}}(\omega)) | \sup_{\omega} | \hat{f}_{T_{k_i}}(\omega) - \bar{f}(\omega) | \to 0.$$
As the above result is true for every sequence \( \{T_k\} \), we have proven (cii).

Above we have shown (the well known result) that spectral density estimator with unknown mean is asymptotically equivalent to the spectral density estimator as if the mean were known. Furthermore, we observe that in the definition of the DFT, we have not subtracted the mean, this is because

\[
\hat{J}_T(\omega_k) = \frac{1}{\sqrt{2\pi T}} \sum_{t=1}^{T} \left( X_t - \mu \right) \exp(-it\omega_k), \quad (A.5)
\]

with \( \mu = E(X_t) \). Therefore

\[
\hat{C}_T(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} \hat{L}(\omega_k)\hat{J}_T(\omega_k)\hat{J}_T(\omega_{k+r}) \hat{L}(\omega_{k+r}) \exp(i\ell\omega_k)
\]

uniformly over all frequencies. In other words, the DFT covariance is asymptotically the same as the DFT covariance constructed as if the mean were known. Therefore, from now onwards, in order to avoid unnecessary notation in the proofs, we will assume that the mean of the time series is zero and the spectral density matrix is estimated using

\[
\hat{f}_T(\omega_k) = \frac{1}{2\pi T} \sum_{t, \tau=1}^{T} \lambda_b(t - \tau) \exp(-i(t - \tau)\omega_k) X_t X'_\tau = \frac{1}{T} \sum_{j=-\left\lfloor \frac{T}{2} \right\rfloor}^{\left\lfloor \frac{T}{2} \right\rfloor} K_b(\omega_k - \omega_j)\hat{J}_T(\omega_j)\hat{J}_T(\omega_j), \quad (A.6)
\]

where \( K_b(\omega_j) = \sum_r \lambda_b(r)e^{-ir\omega_j} \).

### A.2 Proof of Theorems 3.1 and 3.5

The main objective of this section is to prove Theorems 3.1 and 3.5. We will show that in the stationary case the leading term of \( \hat{C}_T(r, \ell) \) is \( \tilde{C}_T(r, \ell) \), whereas in the nonstationary case it is \( \tilde{C}_T(r, \ell) \) plus two additional terms which are defined below. This is achieved by making a Taylor expansion and decomposing the difference \( \hat{C}_T(r, \ell) - \tilde{C}_T(r, \ell) \) into several terms (see Theorem A.3). On first impression, it may seem surprising that in the stationary case the bandwidth \( b \) does not have an influence on the asymptotic distribution of \( \hat{C}_T(r, \ell) \). This can be explained by the decomposition below, where each of these terms are sums of DFTs. The DFTs over their frequencies behave like stochastic process with decaying correlation, how fast correlation decays depends on whether the underlying time series is stationary or not (see Lemmas A.4 and A.8 for the details).

We start by deriving an expression for \( \sqrt{T}[\tilde{c}_{j_1,j_2}(r, \ell) - \tilde{c}_{j_1,j_2}(r, \ell)] \).
Lemma A.3 Suppose that the assumptions in Lemma A.2(c) hold. Then we have

$$\sqrt{T}(\hat{c}_{j_1,j_2}(r, \ell) - \bar{c}_{j_1,j_2}(r, \ell)) = A_{1,1} + A_{1,2} + \sqrt{T}(S_{T,j_1,j_2}(r, \ell) + B_{T,j_1,j_2}(r, \ell)) + O_p(A_2) + O_p(B_2),$$

where

$$A_{1,1} = \frac{1}{\sqrt{T}} \sum_{k=1}^{T} \sum_{s_1,s_2=1}^{d} \left[ J_{k,s_1,s_2} - E(J_{k,s_1,s_2}) \right] \left( \hat{f}_{k,r} - E(\hat{f}_{k,r}) \right) \nabla A_{j_1,s_1,j_2,s_2}(f_{k,r}) e^{i\ell \omega_k},$$

$$A_{1,2} = \frac{1}{\sqrt{T}} \sum_{k=1}^{T} \sum_{s_1,s_2=1}^{d} \left[ J_{k,s_1,s_2} - E(J_{k,s_1,s_2}) \right] \left( E(\hat{f}_{k,r}) - f_{k,r} \right) \nabla A_{j_1,s_1,j_2,s_2}(f_{k,r}) e^{i\ell \omega_k},$$

$$A_2 = \frac{1}{2\sqrt{T}} \sum_{k=1}^{T} \sum_{s_1,s_2=1}^{d} \left| J_{k,s_1,s_2} - E(J_{k,s_1,s_2}) \right| \left| \left( \hat{f}_{k,r} - f_{k,r} \right) \nabla^2 A_{j_1,s_1,j_2,s_2}(f_{k,r}) \right|,$$

$$B_2 = \frac{1}{2\sqrt{T}} \sum_{k=1}^{T} \sum_{s_1,s_2=1}^{d} \left| E(J_{k,s_1,s_2}) \right| \left| \left( \hat{f}_{k,r} - f_{k,r} \right) \nabla^2 A_{j_1,s_1,j_2,s_2}(f_{k,r}) \right|$$

and

$$S_{T,j_1,j_2}(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} \sum_{s_1,s_2=1}^{d} E(J_{k,s_1,s_2})(\hat{f}_{k,r} - E(\hat{f}_{k,r})) \nabla A_{j_1,s_1,j_2,s_2}(f_{k,r}) e^{i\ell \omega_k},$$

$$B_{T,j_1,j_2}(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} \sum_{s_1,s_2=1}^{d} E(J_{k,s_1,s_2})(E(\hat{f}_{k,r}) - f_{k,r}) \nabla A_{j_1,s_1,j_2,s_2}(f_{k,r}) e^{i\ell \omega_k},$$

with $A_{j_1,s_1,j_2,s_2}(f_{k,r})$ defined as in (A.1).

PROOF. We decompose the difference between $\hat{c}_{j_1,j_2}(r, \ell)$ and $\bar{c}_{j_1,j_2}(r, \ell)$ as

$$\sqrt{T}(\hat{c}_{j_1,j_2}(r, \ell) - \bar{c}_{j_1,j_2}(r, \ell))$$

$$= \frac{1}{\sqrt{T}} \sum_{k=1}^{T} \sum_{s_1,s_2=1}^{d} \left[ J_{k,s_1,s_2} - E(J_{k,s_1,s_2}) \right] \left( A_{j_1,s_1,j_2,s_2}(f_{k,r}) - A_{j_1,s_1,j_2,s_2}(f_{k,r}) \right) e^{i\ell \omega_k}$$

$$+ \frac{1}{\sqrt{T}} \sum_{k=1}^{T} \sum_{s_1,s_2=1}^{d} E(J_{k,s_1,s_2})( A_{j_1,s_1,j_2,s_2}(f_{k,r}) - A_{j_1,s_1,j_2,s_2}(f_{k,r}) ) e^{i\ell \omega_k}$$

$$=: I + II.$$

We observe that the difference depends on $A_{j_1,s_1,j_2,s_2}(f_{k,r}) - A_{j_1,s_1,j_2,s_2}(f_{k,r})$, therefore we replace this with the Taylor expansion

$$A(\hat{f}_{k,r}) - A(f_{k,r}) = (\hat{f}_{k,r} - f_{k,r}) \nabla A(f_{k,r}) + \frac{1}{2} (\hat{f}_{k,r} - f_{k,r}) \nabla^2 A(f_{k,r})(\hat{f}_{k,r} - f_{k,r})$$

with $\hat{f}_{k,r}$ lying between $\hat{f}_{k,r}$ and $f_{k,r}$ and $A$ defined as in (A.1) (for clarity, both in the above and for the remainder of the proof we let $A = A_{j_1,s_1,j_2,s_2}$). Substituting the expansion (A.9) into $I$ and $II$ gives
\[ I = A_1 + \hat{A}_2 \] and \[ II = B_1 + \hat{B}_2, \] where
\[
A_1 = \frac{1}{\sqrt{T}} \sum_{k=1}^{T} \sum_{s_1, s_2=1}^{d} \left[ J_{k,s_1} \overline{J_{k+r,s_2}} - E(J_{k,s_1} \overline{J_{k+r,s_2}}) \right] (\hat{f}_{k,r} - f_{k,r})' \nabla A(f_{k,r}) e^{i\omega_k}
\]
\[
B_1 = \frac{1}{\sqrt{T}} \sum_{k=1}^{T} \sum_{s_1, s_2=1}^{d} E(J_{k,s_1} \overline{J_{k+r,s_2}}) (\hat{f}_{k,r} - f_{k,r})' \nabla A(f_{k,r}) e^{i\omega_k}
\]
and
\[
\hat{A}_2 = \frac{1}{2\sqrt{T}} \sum_{k=1}^{T} \sum_{s_1, s_2=1}^{d} \left[ J_{k,s_1} \overline{J_{k+r,s_2}} - E(J_{k,s_1} \overline{J_{k+r,s_2}}) \right] (\hat{f}_{k,r} - f_{k,r})' \nabla^2 A(\hat{f}_{k,r}) (\hat{f}_{k,r} - f_{k,r}) e^{i\omega_k},
\]
\[
\hat{B}_2 = \frac{1}{2\sqrt{T}} \sum_{k=1}^{T} \sum_{s_1, s_2=1}^{d} E(J_{k,s_1} \overline{J_{k+r,s_2}}) (\hat{f}_{k,r} - f_{k,r})' \nabla^2 A(f_{k,r}) (\hat{f}_{k,r} - f_{k,r}) e^{i\omega_k}.
\]

Next we substitute the decomposition \( \hat{f}_{k,r} - f_{k,r} = \overline{f}_{k,r} - E(\overline{f}_{k,r}) + E(\overline{f}_{k,r}) - f_{k,r} \) into \( A_1 \) and \( B_1 \) to obtain \( A_1 = A_{1,1} + A_{1,2} \) and \( B_1 = \sqrt{T} \left[ S_{T,j_1,j_2}(r, \ell) + B_{T,j_1,j_2}(r, \ell) \right] \). Therefore we have \( I = A_{1,1} + A_{1,2} + \hat{A}_2 \) and \( II = \sqrt{T} \left[ S_{T,j_1,j_2}(r, \ell) + B_{T,j_1,j_2}(r, \ell) \right] + \hat{B}_2 \).

Finally, by using Lemma A.2(c), we have
\[
\sup_{\omega_1, \omega_2} \left| \nabla^2 A(\hat{f}_T(\omega_1), \hat{f}_p(\omega_2)) - \nabla^2 A(f(\omega_1), f(\omega_2)) \right| \overset{P}{\to} 0.
\]

Therefore, we take the absolute values of \( \hat{A}_2 \) and \( \hat{B}_2 \), and replace \( \nabla^2 A(f_{k,r}) \) with its deterministic limit \( \nabla^2 A(\hat{f}_{k,r}) \) to give the result. \( \Box \)

To simplify the notation in the rest of this section, we will drop the multivariate suffix and assume that we are in the univariate setting (the proof is identical for the multivariate case). Therefore
\[
\sqrt{T} (\hat{c}(r, \ell) - c(r, \ell)) = A_{1,1} + A_{1,2} + \sqrt{T} \left( S_T(r, \ell) + B_T(r, \ell) \right) + O_p(A_2) + O_p(B_2), \tag{A.10}
\]
where
\[
A_{1,1} = \frac{1}{\sqrt{T}} \sum_{k=1}^{T} \left[ J_k \overline{J_{k+r}} - E(J_k \overline{J_{k+r}}) \right] (\hat{f}_{k,r} - f_{k,r})' G(\omega_k),
\]
\[
A_{1,2} = \frac{1}{\sqrt{T}} \sum_{k=1}^{T} \left[ J_k \overline{J_{k+r}} - E(J_k \overline{J_{k+r}}) \right] (E(\hat{f}_{k,r}) - f_{k,r})' G(\omega_k), \tag{A.11}
\]
\[
S_T(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} E(J_k \overline{J_{k+r}}) (\hat{f}_{k,r} - E(\hat{f}_{k,r}))' G(\omega_k), \tag{A.12}
\]
\[
B_T(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} E(J_k \overline{J_{k+r}}) (E(\hat{f}_{k,r}) - f_{k,r})' G(\omega_k),
\]

50
\[ |A_2| \leq \frac{1}{2\sqrt{T}} \sum_{k=1}^{T} |J_k \overline{J}_{k+r} - E(J_k \overline{J}_{k+r})| : | \hat{f}_{k,r} - f_{k,r}|^2 |H(\omega_k)|_2, \]

\[ |B_2| \leq \frac{1}{2\sqrt{T}} \sum_{k=1}^{T} |E(J_k \overline{J}_{k+r})| : | \hat{f}_{k,r} - f_{k,r}|^2 |H(\omega_k)|_2, \]  

(A.13)

with \(G(\omega_k) = \nabla A(\hat{f}_{k,r})e^{i\omega_k}\) and \(H(\omega_k) = \nabla^2 A(\hat{f}_{k,r})\). In the following lemmas we obtain bounds for each of these terms.

In the proofs below, we will often use the result that if the cumulants are absolutely summable, in the sense that \(\sup_{\omega} \sum_{h_1,\ldots,h_{n-1}} |\text{cum}(X_t, X_{t+h_1}, \ldots, X_{t+h_{n-1}})| < \infty\), then

\[ \sup_{\omega_1,\ldots,\omega_n} \left| \text{cum}(J_T(\omega_1), \ldots, J_T(\omega_n)) \right| \leq \frac{C}{T^{n/2-1}} \]  

(A.14)

for some constant \(C\). In the following lemma, we bound \(A_{1,1}\).

**Lemma A.4** Suppose that for \(1 \leq n \leq 8\), we have \(\sup_{\omega} \sum_{h_1,\ldots,h_{n-1}} |\text{cum}(X_t, X_{t+h_1}, \ldots, X_{t+h_{n-1}})| < \infty\). Let \(A_{1,1}\) be defined as in (A.11).

(i) In addition, suppose that for \(r \neq 0\), we have \(|\text{cov}(J_T(\omega_k), J_T(\omega_{k+r}))| = O(T^{-1})\), then \(\|A_{1,1}\|_2 = O(\frac{1}{\sqrt{T}} + \frac{1}{T})\).

(ii) On the other hand, suppose that \(\sum_{k=1}^{T} |\text{cov}(J_T(\omega_k), J_T(\omega_{k+r}))| \leq C \log T\), then we have \(\|A_{1,1}\|_2 \leq C(\frac{\log T}{\sqrt{T}})\).

**PROOF.** We prove the result in case (ii) (the proof of (i) is a simpler version of this result). By using the spectral representation of the spectral density function in (A.6), we have

\[ A_{1,1} = \frac{1}{T^{3/2}} \sum_{k=1}^{T} \sum_{l=-[\frac{T}{2}]}^{[\frac{T}{2}]} \left( K_b(\omega_k - \omega_l), K_b(\omega_{k+r} - \omega_l) \right) G(\omega_k)(J_k \overline{J}_{k+r} - E(J_k \overline{J}_{k+r}))(|J_l|^2 - E|J_l|^2) \]  

(A.15)

Evaluating the expectation of \(A_{1,1}\) gives

\[ E(A_{1,1}) = \frac{1}{T^{3/2}} \sum_{k=1}^{T} \sum_{l=-[\frac{T}{2}]}^{[\frac{T}{2}]} \left( K_b(\omega_k - \omega_l), K_b(\omega_{k+r} - \omega_l) \right) G(\omega_k) \text{cov}(J_k \overline{J}_{k+r}, J_l \overline{J}_l) \]

\[ = \frac{1}{T^{3/2}} \sum_{k=1}^{T} \sum_{l=-[\frac{T}{2}]}^{[\frac{T}{2}]} \left( K_b(\omega_k - \omega_l), K_b(\omega_{k+r} - \omega_l) \right) G(\omega_k) \]

\[ \times \left( \text{cov}(J_k, J_l) \text{cov}(\overline{J}_{k+r}, \overline{J}_l) + \text{cov}(J_k, J_l) \text{cov}(\overline{J}_{k+r}, J_l) + \text{cum}(J_k, \overline{J}_{k+r}, J_l, J_l) \right) \]

\[ =: I + II + III. \]
By using that \( \sum_{r} E(J_k \bar{J}_{k+r}) \leq C \log T \), we can show \( I, II = O(\frac{\log T}{b_0^2}) \) and by using (A.14), we have \( III = O\left(\frac{1}{\sqrt{T}}\right) \). Altogether, this gives \( E(A_{1,1}) = O(\frac{\log T}{b_0^2}) \) (under the conditions in (i) we have \( E(A_{1,1}) = O\left(\frac{1}{\sqrt{T}}\right) \)).

We now evaluate a bound for \( \text{var}(A_{1,1}) \). Again using (A.15) gives

\[
\text{var}(A_{1,1}) = \frac{1}{T^3} \sum_{k_1, l_1, k_2, l_2} (K_b(\omega_{k_1} - \omega_{l_1}), K_b(\omega_{k_1} + r - \omega_{l_1})) G(\omega_{k_1}) G(\omega_{k_2})' (K_b(\omega_{k_2} - \omega_{l_2}), K_b(\omega_{k_2} + r - \omega_{l_2}))' \\
\times \text{cov}\left( (J_{k_1} \bar{J}_{k_1+r} - E(J_{k_1} \bar{J}_{k_1+r}))(J_{l_1} \bar{J}_{l_1} - E(J_{l_1} \bar{J}_{l_1})), (J_{k_2} \bar{J}_{k_2+r} - E(J_{k_2} \bar{J}_{k_2+r}))(J_{l_2} \bar{J}_{l_2} - E(J_{l_2} \bar{J}_{l_2})) \right).
\]

By using indecomposable partitions (see Brillinger (1981) for the definition) we can show that \( \text{var}(A_{1,1}) = O(\frac{\log T}{T^2}) \) (under (i) it will be \( \text{var}(A_{1,1}) = O\left(\frac{1}{T^2}\right) \)). This gives the desired result. \( \square \)

In the following lemma, we bound \( A_{1,2} \).

**Lemma A.5** Suppose that \( \sup_t \sum_{h_1, h_2, h_3} |\text{cum}(X_t, X_{t+h_1}, X_{t+h_2}, X_{t+h_3})| < \infty \). Let \( A_{1,2} \) be defined as in (A.11).

(i) In addition, suppose that for \( r \neq 0 \) we have \( |\text{cov}(J_T(\omega_k), J_T(\omega_{k+r}))| = O(T^{-1}) \), then \( \|A_{1,2}\|_2 \leq C \sup_\omega |E(\hat{f}_T(\omega)) - f(\omega)| \).

(ii) On the other hand, suppose that \( \sum_{k=1}^T |\text{cov}(J_T(\omega_k), J_T(\omega_{k+r}))| \leq C \log T \), then we have \( \|A_{1,2}\|_2 \leq C \log T \sup_\omega |E(\hat{f}_T(\omega)) - f(\omega)| \).

**PROOF.** Since the mean of \( A_{1,2} \) is zero, we evaluate the variance

\[
\text{var}\left( \frac{1}{\sqrt{T}} \sum_{k=1}^T h_k (J_k \bar{J}_{k+r} - E(J_k \bar{J}_{k+r})) \right) = \frac{1}{T} \sum_{k_1, k_2=1}^T h_{k_1} h_{k_2} \text{cov}(J_{k_1} \bar{J}_{k_1+r}, J_{k_2} \bar{J}_{k_2+r}) \\
= \frac{1}{T} \sum_{k_1, k_2=1}^T h_{k_1} h_{k_2} \left\{ \text{cov}(J_{k_1}, J_{k_2}) \text{cov}(\bar{J}_{k_1+r}, \bar{J}_{k_2+r}) + \text{cov}(J_{k_1}, \bar{J}_{k_2+r}) \text{cov}(\bar{J}_{k_1+r}, J_{k_2}) + \text{cum}(J_{k_1}, \bar{J}_{k_1+r}, J_{k_2}, \bar{J}_{k_2+r}) \right\},
\]

where \( h_k = (E(\hat{J}_{k,r}) - \hat{f}_{k,r})' G(\omega_k) \). Therefore, under the stated conditions, and by using (A.14), the result immediately follows. \( \square \)

In the following lemma, we bound \( A_2 \) and \( B_2 \).

**Lemma A.6** Suppose \( \{X_t\}_t \) is a time series where for \( n = 2, \ldots, 8 \), we have

\( \sup_t \sum_{h_1, \ldots, h_{n-1}} |\text{cum}(X_t, X_{t+h_1}, \ldots, X_{t+h_{n-1}})| < \infty \) and the assumptions of Lemma A.2 are satisfied. Then

\[
\|J_k \bar{J}_{k+r} - E(J_k \bar{J}_{k+r})\|_2 = O(1)
\] (A.16)
Therefore, by using sup

\[ \rho \leq b^2 \sqrt{T} \]

Thus, by using (A.16) and Lemma A.2(a,b), we have (A.17).

PROOF. We have

\[ J_k J_k^* - E(J_k J_k^*) = \frac{1}{2\pi T} \sum_{t, r=1}^{T} \rho_{t, r}(X_t X_r - E(X_t X_r)) \]

where \( \rho_{t, r} = \exp(-i \omega_k (t - r)) \exp(i \omega_r r) \). Now, by evaluating the variance, we get

\[ E|J_k J_k^* - E(J_k J_k^*)|^2 \leq \frac{1}{(2\pi)^2} (I + II + III), \]

where

\[ I = T^{-2} \sum_{t_1, t_2=1}^{T} \sum_{r_1, r_2=1}^{T} \rho_{t_1, r_1} \rho_{t_2, r_2} \text{cov}(X_{t_1}, X_{t_2}) \text{cov}(X_{r_1}, X_{r_2}), \]

\[ II = T^{-2} \sum_{t_1, t_2=1}^{T} \sum_{r_1, r_2=1}^{T} \rho_{t_1, r_1} \rho_{t_2, r_2} \text{cov}(X_{t_1}, X_{r_2}) \text{cov}(X_{r_1}, X_{t_2}), \]

\[ III = T^{-2} \sum_{t_1, t_2=1}^{T} \sum_{r_1, r_2=1}^{T} \rho_{t_1, r_1} \rho_{t_2, r_2} \text{cum}(X_{t_1}, X_{r_1}, X_{t_2}, X_{r_2}). \]

Therefore, by using sup \( \sum_r |\text{cov}(X_{t}, X_r)| < \infty \) and sup \( \sum_{r_1, r_2, r_3} |\text{cum}(X_{t}, X_{r_1}, X_{r_2}, X_{r_3})| < \infty \), we have (A.16).

To obtain bounds for \( A_2 \) and \( B_2 \), we get from (A.13) and Cauchy-Schwarz inequality

\[ \|A_2\|_1 \leq \frac{1}{\sqrt{2T}} \sum_{k=1}^{T} \|J_k J_k^* - E(J_k J_k^*)\|_2 \cdot \|\hat{f}_{k,r} - \tilde{f}_{k,r}\|^2_2 H(\omega_k)\|_2, \]

\[ \|B_2\|_1 \leq \frac{1}{2\sqrt{T}} \sum_{k=1}^{T} |E(J_k J_k^*)| \cdot \|\hat{f}_{k,r} - \tilde{f}_{k,r}\|^2_2 H(\omega_k)\|_2. \]

Thus, by using (A.16) and Lemma A.2(a,b), we have (A.17).

Finally, we obtain bounds for \( \sqrt{T} S_T(r, \ell) \) and \( \sqrt{T} B_T(r, \ell) \).

**Lemma A.7** Suppose \( \{X_t\}_t \) is a time series whose cumulants satisfy sup \( \sum_{h} |\text{cov}(X_t, X_{t+h})| < \infty \) and sup \( \sum_{h_1, h_2, h_3} |\text{cum}(X_t, X_{t+h_1}, X_{t+h_2}, X_{t+h_3})| < \infty \).

(i) If \( |E(J_T(\omega_k) J_T(\omega_k+r))| = O(\frac{1}{T}) \) for all \( k \) and \( r \neq 0 \), then

\[ \|S_T(r, \ell)\|_2 = O \left( \frac{1}{b^{1/2} T^{3/2}} \right) \text{ and } |B_T(r, \ell)| = O \left( \frac{b}{T} \right). \]
(ii) On the other hand, if for fixed \( r \) and \( k \) we have \(|E(J_T(\omega_k)\tilde{J}_T(\omega_{k+r}))| = h(\omega_k; r) + O(\frac{1}{T})\) (where \( h(\cdot, r) \) is a function with a bounded derivative over \([0, 2\pi]\)) and the conditions in Lemma A.2(a) hold, then we have

\[
\|S_T(r, \ell)\|_2 = O(T^{-1/2}) \quad \text{and} \quad |B_T(r, \ell)| = O(b).
\]

PROOF. We first prove (i). Bounding \(|S_T(r, \ell)\|_2\) and \(|B_T(r, \ell)|\) gives

\[
\|S_T(r, \ell)\|_2 \leq \frac{1}{T} \sum_{k=1}^{T} \left|E(J_k\tilde{J}_{k+r})\right| \left\|\hat{f}_{k,r} - E(\hat{f}_{k,r})\right\|_2 |G(\omega_k)|_2,
\]

\[
|B_T(r, \ell)| = \frac{1}{T} \sum_{k=1}^{T} \left|E(J_k\tilde{J}_{k+r})\right| \left|E(\hat{f}_{k,r}) - f_{k,r}\right| |G(\omega_k)|_1
\]

and by substituting the bounds in Lemma A.2(a) and \(|E(J_k\tilde{J}_{k+r})| = O(T^{-1})\) into the above, we obtain (i).

The proof of (ii) is rather different. We don’t obtain the same bounds as in (i), because we do not have \(|E(J_k\tilde{J}_{k+r})| = O(T^{-1})\). To bound \(S_T(r, \ell)\), we rewrite it as a quadratic form (see Section A.4 for the details)

\[
S_T(r, \ell) = \frac{-1}{2T} \sum_{k=1}^{T} E(J_k\tilde{J}_{k+r}) \exp(i\ell\omega_k) \left( \frac{\hat{f}_T(\omega_k) - E(\hat{f}_T(\omega_k))}{\sqrt{f(\omega_k)f(\omega_{k+r})}} + \frac{\hat{f}_T(\omega_{k+r}) - E(\hat{f}_T(\omega_{k+r}))}{\sqrt{f(\omega_k)f(\omega_{k+r})}} \right)
\]

\[
= \frac{-1}{2T} \sum_{k=1}^{T} h(\omega_k, r) \exp(i\ell\omega_k) \left( \frac{\hat{f}_T(\omega_k) - E(\hat{f}_T(\omega_k))}{\sqrt{f(\omega_k)f(\omega_{k+r})}} + \frac{\hat{f}_T(\omega_{k+r}) - E(\hat{f}_T(\omega_{k+r}))}{\sqrt{f(\omega_k)f(\omega_{k+r})}} \right) + O\left(\frac{1}{T}\right)
\]

\[
= \frac{-1}{2T} \sum_{t, \tau} \lambda_b(t - \tau)(X_tX_\tau - E(X_tX_\tau)) \frac{1}{T} \sum_{k=1}^{T} h(\omega_k, r) e^{i\ell\omega_k} \left( \frac{e^{-i(t-\tau)\omega_k}}{\sqrt{f(\omega_k)f(\omega_{k+r})}} + \frac{e^{-i(t-\tau)\omega_{k+r}}}{\sqrt{f(\omega_k)f(\omega_{k+r})}} \right) + O\left(\frac{1}{T}\right)
\]

with \(d_T(\nu; \omega_r) = d(\nu; \omega_r) + O(\frac{1}{T})\), where \(d(\nu; \omega_r)\) as defined in Lemma A.12 (for the case \(d = 1\)). There, we show that \(|d(\nu; \omega_r)| = O(\frac{1}{\sqrt{T}})\) such that \(d_T(\nu; \omega_r) = O(\frac{1}{T} + \frac{1}{T})\) (for \(\nu \neq 0\)). Using this we can show that \(\text{var}(S_T(r, \ell)) = O(T^{-1})\). The bound on \(B_T(r, \ell)\) follows again from Lemma A.2(a).

Having obtained bounds for all the terms in Lemma A.3 (see also equation (A.10)), we now show that Assumptions 3.1 and 3.2 satisfy the conditions under which we obtain these bounds.

Lemma A.8

(i) Suppose \(\{X_t\}\) is a second order stationary time series with \(\sum_h |\text{cov}(X_h, X_0)| < \infty\). Then, we have \(\max_{1 \leq k \leq T} |\text{cov}(J_T(\omega_k), J_T(\omega_{k+r}))| = O(\frac{1}{T})\) for \(r \neq 0, T/2, T\).

(ii) Suppose Assumption 3.2(L2) holds. Then, we have

\[
\text{cov}(J_T(\omega_{k_1}), J_T(\omega_{k_2})) = h(\omega_{k_1}; k_2 - k_1) + R_T(\omega_{k_1}, \omega_{k_2}),
\]

where \(h(\omega; r)\) is defined in Remark 3.2 and \(\sup_{\omega_1, \omega_2} |R_T(\omega_1, \omega_2)| = O(T^{-1})\).
PROOF. (i) follows from (Brillinger, 1981), Theorem 4.3.2.

To prove (ii) under local stationarity, we expand \( \text{cov}(J_{k_1}, J_{k_2}) \) to give

\[
\text{cov}(J_{k_1}, J_{k_2}) = \frac{1}{2\pi T} \sum_{t, \tau = 1}^T \text{cov}(X_{t, \tau}, X_{\tau, T}) \exp(-i(t - \tau)\omega_{k_1} - i\tau(\omega_{k_1} - \omega_{k_2})).
\]

Now, using Assumption 3.2(L2), we can replace \( \text{cov}(X_{t, \tau}, X_{\tau, T}) \) with \( \kappa(T; t - \tau) \) to give

\[
\text{cov}(J_{k_1}, J_{k_2}) = \frac{1}{2\pi T} \sum_{t, \tau = 1}^T \kappa \left( \frac{T}{T}; t - \tau \right) \exp(-i(t - \tau)\omega_{k_1}) \exp(-i\tau(\omega_{k_1} - \omega_{k_2})) + R_1(\omega_{k_1}, \omega_{k_2})
\]

and by using Assumption 3.2(L2), we can replace \( \text{cov} \) in Assumption 3.2(L2) with \( \kappa(T; t - \tau) \) to give

\[
\text{cov}(J_{k_1}, J_{k_2}) = \frac{1}{2\pi T} \sum_{t, \tau = 1}^T \exp(-i\tau(\omega_{k_1} - \omega_{k_2})) \sum_{h = -\tau + 1}^{T - \tau} \kappa \left( \frac{T}{T}; h \right) \exp(-ih\omega_{k_1}) + R_1(\omega_{k_1}, \omega_{k_2})
\]

and by using Assumption 3.2(L2), we can show that \( |R_1(\omega_{k_1}, \omega_{k_2})| \leq \frac{C}{T} \sum_h \kappa_2(h) = O(T^{-1}) \). Next we replace the inner sum with \( \sum_{h = -\infty}^{\infty} \) to give

\[
\text{cov}(J_{k_1}, J_{k_2}) = \frac{1}{T} \sum_{\tau = 1}^T f \left( \frac{T}{T}; \omega_{k_1} \right) \exp \left( i2\pi(k_2 - k_1)\frac{T}{T} \right) + R_1(\omega_{k_1}, \omega_{k_2}) + R_2(\omega_{k_1}, \omega_{k_2}),
\]

where

\[
R_2(\omega_{k_1}, \omega_{k_2}) = \frac{1}{2\pi T} \sum_{\tau = 1}^T \exp(-i\tau(\omega_{k_1} - \omega_{k_2})) \left( \sum_{h = -\infty}^{T - \tau} \sum_{T - \tau + 1}^{\infty} \kappa \left( \frac{T}{T}; h \right) \exp(-ih\omega_{k_1}) \right)
\]

Under Assumption 3.2(L2), we have that \( \sup_t |\kappa(u, h)| \leq C|h|^{-(2+\varepsilon)} \), therefore \( |R_2(\omega_{k_1}, \omega_{k_2})| \leq CT^{-1} \).

Finally, by replacing the sum by an integral, we get

\[
\text{cov}(J_{k_1}, J_{k_2}) = \int_0^1 f(u; \omega_{k_1}) \exp \left( i2\pi(k_2 - k_1)u \right) du + R_T(\omega_{k_1}, \omega_{k_2}),
\]

where \( |R_T(\omega_{k_1}, \omega_{k_2})| \leq CT^{-1} \), which gives (A.19). \( \square \)

In the following lemma and corollary, we show how the \( \alpha \)-mixing rates are related to summability of the cumulants. We state the results for the multivariate case.

**Lemma A.9** Let us suppose that \( \{X_t\} \) is an \( \alpha \)-mixing time series with rate \( K|t|^{-\alpha} \) such that there exists an \( r \) where \( \|X_t\|_r < \infty \) and \( \alpha > r(k - 1)/(r - k) \). If \( t_1 \leq t_2 \leq \ldots \leq t_k \), then we have

\[
|\text{cum}(X_{t_1, j_1}, \ldots, X_{t_k, j_k})| \leq C_k \sup_{t, j} \|X_{t, j}\|_r \prod_{i=2}^k |t_i - t_{i-1}|^{-\alpha(\frac{1}{r-1})},
\]

\[
\sup_{t_1} \sum_{t_2, \ldots, t_k = 1}^\infty |\text{cum}(X_{t_1, j_1}, \ldots, X_{t_k, j_k})| \leq C_k \sup_{t, j} \|X_{t, j}\|_r \left( \sum_{t_1}^k |t_i|^{-\alpha(\frac{1}{r-1})} \right)^{k-1} < \infty. \quad (A.20)
\]

If \( \alpha > 2r(k - 1)/(r - k) \), we have

\[
\sup_{t_1} \sum_{t_2, \ldots, t_k = 1}^\infty (1 + |t_j|)|\text{cum}(X_{t_1, j_1}, \ldots, X_{t_k, j_k})| \leq C_k \sup_{t, j} \|X_{t, j}\|_r \left( \sum_{t_1}^k |t_i|^{-\alpha(\frac{1}{r-1}) + 1} \right)^{k-1} < \infty, \quad (A.21)
\]

where \( C_k \) is a finite constant which depends only on \( k \).
PROOF. The proof is identical to the proof of Lemma 4.1 in Lee and Subba Rao (2011) (see also Statulevicius and Jakimavicius (1988) and Neumann (1996)).

**Corollary A.1** Suppose Assumption 3.1(P1, P2) or 3.2(L1, L3) holds. Then there exists an \( \varepsilon > 0 \) such that \(|\text{cov}(\tilde{X}_0, \tilde{X}_i)| < C|h|^{-2(2+\varepsilon)}\), sup, \(|\text{cov}(\tilde{X}_i, \tilde{X}_i+h,T)| < C|h|^{-2(2+\varepsilon)}\) and

\[
\sup_{t_1,j_1,...,j_4} (1+|t_4|) \cdot |\text{cum}(X_{t_1,j_1}, X_{t_2,j_2}, X_{t_3,j_3}, X_{t_4,j_4})| < \infty, \quad i = 1, 2, 3,
\]

Furthermore, if Assumption 3.1(P1, P4) or 3.2(L1, L5) holds, then for \( 1 \leq n \leq 8 \) we have

\[
\sup_{t_1, t_2,..., t_n} |\text{cum}(X_{t_1,j_1}, X_{t_2,j_2}, ..., X_{t_n,j_n})| < \infty.
\]

PROOF. The proof immediately follows from Lemma A.9, thus we omit the details.

We can now obtain bounds for the difference \(|\sqrt{T}(\hat{c}(r, \ell) - \bar{c}(r, \ell))|\) which leads to the proofs of Theorems 3.1 and 3.5.

**Theorem A.1** Suppose that Assumption 3.1 holds, then we have

\[
\sqrt{T}\hat{c}(r, \ell) = \sqrt{T}\bar{c}(r, \ell) + O_p\left(\frac{1}{b\sqrt{T}} + b + b^2\sqrt{T}\right).
\] \hspace{1cm} (A.22)

Under Assumption 3.2, we have

\[
\sqrt{T}\hat{c}(r, \ell) = \sqrt{T}\bar{c}(r, \ell) + \sqrt{T}S_T(r, \ell) + \sqrt{T}B_T(r, \ell) + O_p\left(\frac{\log T}{b\sqrt{T}} + b\log T + b^2\sqrt{T}\right).
\] \hspace{1cm} (A.23)

PROOF. To prove (A.22), we use the expansion (A.10) to give

\[
\sqrt{T}(\hat{c}(r, \ell) - \bar{c}(r, \ell)) = A_{1,1} + A_{1,2} + O_p(A_2) + O_p(B_2) + \sqrt{T}(S_T(r, \ell) + B_T(r, \ell))
\]

\[
= O\left(\frac{1}{T^{1/2}} + \frac{1}{bT} + b + \frac{1}{b\sqrt{T}} + b^2\sqrt{T} + \frac{b}{\sqrt{T}}\right).
\]

To prove (A.23) we first note that by Lemma A.7(ii) we have \(|S_T(r, \ell)|_2 = O(T^{-1/2})\) and \(|B_T(r, \ell)| = O(b)\), therefore we use expansion (A.10) to give

\[
\sqrt{T}(\hat{c}(r, \ell) - \bar{c}(r, \ell) - S_T(r, \ell) + B_T(r, \ell)) = A_{1,1} + A_{1,2} + O_p(A_2) + O_p(B_2)
\]

\[
= O\left(\frac{\log T}{b\sqrt{T}} + b\log T + \frac{1}{b\sqrt{T}} + b^2\sqrt{T}\right).
\]

This proves the result.

**Proof of Theorems 3.1 and 3.5** The proofs of Theorems 3.1 and 3.5 follow immediately from Theorem A.1.
A.3 Proof of Theorem 3.2 and Lemma 3.1

Throughout the proof, we will assume that $T$ is sufficiently large, i.e. such that $0 < r < \frac{T}{2}$ and $0 < \ell < \frac{T}{2}$ hold. This avoids issues related to symmetry and periodicity of the DFTs. The proof relies on the following important lemma. We mention, that unlike the previous (and future) sections in the Appendix, we will prove the result for the multivariate case. This is because for the variance calculation there are subtle differences between the multivariate and univariate cases.

Lemma A.10 Suppose that $\{X_i\}$ is fourth order stationary such that $\sum_{h} |h| \cdot |\text{cov}(X_{0,j_1}, X_{h,j_2})| < \infty$ and $\sum_{h_1,h_2,h_3} |h_1| \cdot |\text{cum}(X_{0,j_1}, X_{h_1,j_2}, X_{h_2,j_3}, X_{h_3,j_4})| < \infty$ hold for all $j_1, \ldots, j_4 = 1, \ldots, d$ and $i = 1, 2, 3$. We mention that these conditions are satisfied under Assumption 3.1(P1,P2) (see Corollary A.1). Then, for all fixed $r_1, r_2 \in \mathbb{N}$ and $\ell_1, \ell_2 \in \mathbb{N}_0$ and all $j_1, j_2, j_3, j_4 \in \{1, \ldots, d\}$, we have

\[
T \text{cov} (\tilde{c}_{j_1,j_2}(r_1, \ell_1), \tilde{c}_{j_3,j_4}(r_2, \ell_2)) = \left\{ \begin{array}{ll}
\delta_{j_1,j_2} \delta_{j_3,j_4} \delta_1 \delta_{r_1} + \delta_{j_1,j_2} \delta_{j_3,j_4} \delta_1 \delta_{r_2} & \delta_{r_1} = \delta_{r_2} \\
\delta_{j_1,j_2} \delta_{j_3,j_4} & \delta_{r_1} \neq \delta_{r_2}
\end{array} \right.
\]

where $\delta_{jk} = 1$ if $j = k$ and $\delta_{jk} = 0$ otherwise. As both right-hand sides above are unaffected by complex conjugation, $T \text{cov}(\tilde{c}_{j_1,j_2}(r_1, \ell_1), \tilde{c}_{j_3,j_4}(r_2, \ell_2))$ and $T \text{cov}(\tilde{c}_{j_1,j_2}(r_1, \ell_1), \tilde{c}_{j_3,j_4}(r_2, \ell_2))$ satisfy the same properties, respectively.

PROOF. Straightforward calculations give

\[
T \text{cov} (\tilde{c}_{j_1,j_2}(r_1, \ell_1), \tilde{c}_{j_3,j_4}(r_2, \ell_2)) = \frac{1}{T} \sum_{k_1,k_2=1}^{T} \sum_{s_1,s_2,s_3,s_4=1}^{d} L_{j_1,s_1}(\omega_{k_1}) L_{j_2,s_2}(\omega_{k_1+1}) L_{j_3,s_3}(\omega_{k_2}) L_{j_4,s_4}(\omega_{k_2+1}) \times \text{cov}(J_{k_1,s_1}, J_{k_1+s_1,s_2}, J_{k_2,s_3}, J_{k_2+s_3,s_4}) \exp(i\ell_1 \omega_{k_1} - i\ell_2 \omega_{k_2}),
\]

and by using the identity $\text{cum}(Z_1, Z_2, Z_3, Z_4) = \text{cov}(Z_1 \bar{Z}_2, Z_3 \bar{Z}_4) - E(Z_1 \bar{Z}_3)E(Z_2 \bar{Z}_4) - E(Z_1 \bar{Z}_4)E(Z_2 \bar{Z}_3)$ for complex-valued and zero mean random variables $Z_1, Z_2, Z_3, Z_4$, we get

\[
T \text{cov}(\tilde{c}_{j_1,j_2}(r_1, \ell_1), \tilde{c}_{j_3,j_4}(r_2, \ell_2)) = \frac{1}{T} \sum_{k_1,k_2=1}^{T} \sum_{s_1,s_2,s_3,s_4=1}^{d} L_{j_1,s_1}(\omega_{k_1}) L_{j_2,s_2}(\omega_{k_1+1}) L_{j_3,s_3}(\omega_{k_2}) L_{j_4,s_4}(\omega_{k_2+1}) \left\{ E(J_{k_1,s_1}, J_{k_2,s_3}) E(J_{k_1+s_1,s_2}, J_{k_2+s_3,s_4}) + \text{cum}(J_{k_1,s_1}, J_{k_1+s_1,s_2}, J_{k_2,s_3}, J_{k_2+s_3,s_4}) \right\} \exp(i\ell_1 \omega_{k_1} - i\ell_2 \omega_{k_2}) =: I + II + III.
\]
where used. Using similar arguments, we obtain

\[ \sum_{t=1}^{T} e^{-it(\omega_{k1} - \omega_{k2})} \] gives

\[ I = \frac{1}{T} \sum_{k_1, k_2 = 1}^{d} \sum_{s_1, s_2, s_3, s_4 = 1}^{d} L_{j_1 s_1} (\omega_{k1}) L_{j_2 s_2} (\omega_{k1+r_1}) L_{j_3 s_3} (\omega_{k2}) L_{j_4 s_4} (\omega_{k2+r_2}) \]

\[ \times \left( \frac{1}{2\pi T} \sum_{h = -(T-1)}^{T-1} \kappa_{s_1 s_3} (h) e^{-i\omega_{k2}} \left( \sum_{t=1}^{T} e^{-it(\omega_{k1} - \omega_{k2})} + O(h) \right) \right) \]

\[ \times \left( \frac{1}{2\pi T} \sum_{h = -(T-1)}^{T-1} \kappa_{s_2 s_4} (h) e^{i\omega_{k2+r_2}} \left( \sum_{t=1}^{T} e^{it(\omega_{k1+r_1} - \omega_{k2+r_2})} + O(h) \right) \exp(i\ell_1 \omega_{k1} - i\ell_2 \omega_{k2}) \right), \]

where it is clear that the \( O(h) \) term is uniformly bounded over all frequencies and \( h \). Due to \( \sum_h |\kappa_{s_1 s_3} (h)| < \infty \), we have

\[ I = \frac{1}{T} \sum_{k_1, k_2 = 1}^{d} \left( \sum_{s_1, s_3 = 1}^{d} L_{j_1 s_1} (\omega_{k1}) f_{s_1 s_3} (\omega_{k2}) L_{j_3 s_3} (\omega_{k2}) \exp(i\ell_1 \omega_{k1}) \right) \]

\[ \times \left( \sum_{s_2, s_4 = 1}^{d} L_{j_2 s_2} (\omega_{k1+r_1}) f_{s_2 s_4} (\omega_{k2+r_2}) L_{j_4 s_4} (\omega_{k2+r_2}) \exp(-i\ell_2 \omega_{k2}) \right) \delta_{k_1 k_2} \delta_{r_1 r_2} + O \left( \frac{1}{T} \right) \]

where \( L(\omega_k) f(\omega_k) L(\omega_k)' = \mathbf{1}_d \) and \( \frac{1}{T} \sum_{t=1}^{T} \exp(-i(\ell_1 - \ell_2)\omega_k) = 1 \) if \( \ell_1 = \ell_2 \) and zero otherwise have been used. Using similar arguments, we obtain

\[ II = \frac{1}{T} \sum_{k_1, k_2 = 1}^{d} \left( \sum_{s_1, s_4 = 1}^{d} L_{j_1 s_1} (\omega_{k1}) f_{s_1 s_4} (\omega_{k2+r_2}) L_{j_4 s_4} (\omega_{k2+r_2}) \exp(i\ell_1 \omega_{k1}) \right) \]

\[ \times \left( \sum_{s_2, s_3 = 1}^{d} L_{j_2 s_2} (\omega_{k1+r_1}) f_{s_2 s_3} (\omega_{k2}) L_{j_3 s_3} (\omega_{k2}) \exp(-i\ell_2 \omega_{k2}) \right) \delta_{k_1 k_2} \delta_{r_1 r_2} + O \left( \frac{1}{T} \right) \]

\[ = \delta_{j_1 j_3} \delta_{j_2 j_4} \delta_{r_1 r_2} \delta_{\ell_1, \ell_2} + O \left( \frac{1}{T} \right), \]
where \( \exp(-i\ell_2\omega_{r_1}) \to 1 \) as \( T \to \infty \) and \( \frac{1}{T}\sum_{k=1}^{T} \exp(-i(\ell_1 + \ell_2)\omega_k) = 1 \) if \( \ell_1 = -\ell_2 \) and zero otherwise have been used. Finally, by using Theorem 4.3.2, (Brillinger, 1981), we have

\[
III = \frac{1}{T} \sum_{k_1,k_2=1}^{T} \sum_{s_1,s_2,s_3,s_4=1}^{d} L_{j_1,s_1}(\omega_k) L_{j_2,s_2}(\omega_{k+r_1}) L_{j_3,s_3}(\omega_k) L_{j_4,s_4}(\omega_{k+r_2}) \exp(i\ell_1\omega_k - i\ell_2\omega_{k+r_2})
\]

\[
\times \left( \frac{2\pi}{T^2} \int_{0}^{2\pi} f_{4,s_1,s_2,s_3,s_4}(\omega_k,-\omega_{k+r_1},-\omega_{k+r_2}) \exp(i\ell_1\omega_k - i\ell_2\omega_{k+r_2}) \right)
\]

\[
\times \left( \frac{2\pi}{T^2} \int_{0}^{2\pi} \sum_{s_1,s_2,s_3,s_4=1}^{d} L_{j_1,s_1}(\omega_k) L_{j_2,s_2}(\omega_{k+r_1}) L_{j_3,s_3}(\omega_k) L_{j_4,s_4}(\omega_{k+r_2}) \exp(i\ell_1\omega_k - i\ell_2\omega_{k+r_2}) \right)
\]

\[
\times \left( \frac{1}{2\pi} \int_{0}^{2\pi} \sum_{s_1,s_2,s_3,s_4=1}^{d} L_{j_1,s_1}(\lambda_1) L_{j_2,s_2}(\lambda_1) L_{j_3,s_3}(\lambda_2) L_{j_4,s_4}(\lambda_2) \exp(i\ell_1\lambda_1 - i\ell_2\lambda_2) \right)
\]

\[
\times \left( \frac{1}{2\pi} \int_{0}^{2\pi} \sum_{s_1,s_2,s_3,s_4=1}^{d} L_{j_1,s_1}(\lambda_1) L_{j_2,s_2}(\lambda_1) L_{j_3,s_3}(\lambda_2) L_{j_4,s_4}(\lambda_2) \exp(i\ell_1\lambda_1 - i\ell_2\lambda_2) \right)
\]

\[
= \kappa^{(\ell_1,\ell_2)}(j_1,j_2,j_3,j_4) \delta_{r_1r_2} + O\left( \frac{1}{T} \right),
\]

which gives the first claimed equality. In the computations for the second equality of this lemma, a \( \delta_{r_1,-r_2} \) crops up, which is always zero due to \( r_1, r_2 \in \mathbb{N} \). Further, as \( \kappa^{(\ell_1,\ell_2)}(j_1,j_2,j_3,j_4) \) is real-valued by Lemma A.11 below, this immediately implies the second assertion. \( \square \)

**PROOF of Theorem 3.2**

To prove part (i), we consider the entries of \( \tilde{C}_T(r,\ell) \)

\[
E(\tilde{c}_{j_1,j_2}(r,\ell)) = \frac{1}{T} \sum_{k=1}^{T} \sum_{s_1,s_2=1}^{d} L_{j_1,s_1}(\omega_k) E(J_{k,s_1}J_{k+r,s_2}) L_{j_2,s_2}(\omega_{k+r}) \exp(i\omega_k\ell)
\]

and using Lemma A.8(i) yields \( E(J_{k,s_1}J_{k+r,s_2}) = O\left( \frac{1}{T} \right) \) for \( r \neq Tk, k \in \mathbb{Z} \), which gives the assertion. Part (ii) follows from \( \Re Z = \frac{1}{2}(Z + \overline{Z}) \), \( \Im Z = \frac{1}{2i}(Z - \overline{Z}) \) and Lemma A.10. \( \square \)

**Lemma A.11** For \( \kappa^{(\ell_1,\ell_2)}(j_1,j_2,j_3,j_4) \) defined in (2.15), we have

\[
\kappa^{(\ell_1,\ell_2)}(j_1,j_2,j_3,j_4) = \kappa^{(\ell_2,\ell_1)}(j_1,j_2,j_3,j_4) = \kappa^{(\ell_2,\ell_1)}(j_3,j_4,j_1,j_2)
\]

(A.24)

In particular, \( \kappa^{(\ell_1,\ell_2)}(j_1,j_2,j_3,j_4) \) is always real-valued. Furthermore, (A.24) causes the limits of the variances \( \var{\sqrt{T} \text{vec} \left( \Re \tilde{C}_T(r,0) \right)} \) and \( \var{\sqrt{T} \text{vec} \left( \Im \tilde{C}_T(r,0) \right)} \) to be singular.

**Proof.** By substituting \( \lambda_1 \to -\lambda_1 \) and \( \lambda_2 \to -\lambda_2 \) in \( \kappa^{(\ell_1,\ell_2)}(j_1,j_2,j_3,j_4) \), \( L_{j\lambda}(-\lambda) = L_{j\lambda}(\lambda) \) and \( f_{k,s_1,s_2,s_3,s_4}(-\lambda_1,\lambda_1,\lambda_2) = f_{k,s_1,s_2,s_3,s_4}(\lambda_1,-\lambda_1,-\lambda_2) \), we get the first identity in (A.24). The second follows from exchanging variable denotation of \( \lambda_1 \) and \( \lambda_2 \) and reordering terms in \( \kappa^{(\ell_1,\ell_2)}(j_1,j_2,j_3,j_4) \) and
from $f_{4,s_1,s_2,s_3,s_4}(\lambda_2,-\lambda_2,-\lambda_1) = f_{4,s_3,s_4,s_1,s_2}(\lambda_1,-\lambda_1,-\lambda_2)$. The first identity immediately implies that $\kappa^{(\ell_1,\ell_2)}(j_1,j_2,j_3,j_4)$ is real-valued. To prove the second part of this lemma, we consider only the real part of $\tilde{C}_T(r,0)$ and we can assume wlog that $d = 2$. From Lemma A.10, we get immediately

\[
\var \left( \sqrt{T} \text{vec} \left( \Re \tilde{C}_T(r,0) \right) \right) \to \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & \frac{1}{2} & \frac{1}{2} & 0 \\
0 & \frac{1}{2} & \frac{1}{2} & 0 \\
0 & 0 & 0 & 1
\end{pmatrix} + \frac{1}{2} \begin{pmatrix}
\kappa^{(0,0)}(1,1,1) & \kappa^{(0,0)}(1,1,2) & \kappa^{(0,0)}(1,1,2) & \kappa^{(0,0)}(1,1,2) \\
\kappa^{(0,0)}(2,1,1) & \kappa^{(0,0)}(2,1,2) & \kappa^{(0,0)}(2,1,2) & \kappa^{(0,0)}(2,1,2) \\
\kappa^{(0,0)}(1,2,1) & \kappa^{(0,0)}(1,2,2) & \kappa^{(0,0)}(1,2,2) & \kappa^{(0,0)}(1,2,2) \\
\kappa^{(0,0)}(2,2,1) & \kappa^{(0,0)}(2,2,2) & \kappa^{(0,0)}(2,2,2) & \kappa^{(0,0)}(2,2,2)
\end{pmatrix},
\]

and due to (A.24), the second and third rows are equal leading to singularity. 

**PROOF of Lemma 3.1** By using Lemma A.8(ii) (generalized to the multivariate setting) we have

\[
E(\tilde{C}_T(r,\ell)) = \frac{1}{T} \sum_{k=1}^{T} L(\omega_k) E(L_T(\omega_k)L_T(\omega_k) \exp(i\lambda \omega_k))
\]

\[
= \frac{1}{T} \sum_{k=1}^{T} L(\omega_k) \left( \int_{0}^{1} f(u;\omega_k) \exp(2\pi i r u) du \right) L(\omega_k) \exp(i\lambda \omega_k) + O \left( \frac{1}{T} \right) \quad \text{(by (A.19))}
\]

\[
= \frac{1}{2\pi} \int_{0}^{2\pi} L(\omega) \left( \int_{0}^{1} f(u;\omega) \exp(2\pi i r u) du \right) L(\omega + \omega_r) \exp(i\lambda \omega) d\omega + O \left( \frac{1}{T} \right)
\]

\[
= \frac{1}{2\pi} \int_{0}^{2\pi} \int_{0}^{1} L(\omega) f(u;\omega) L(\omega) \exp(2\pi i r u) du \exp(i\lambda \omega) d\omega + O \left( \frac{1}{T} \right)
\]

\[
= \mathbf{A}(r,\ell) + O \left( \frac{1}{T} \right).
\]

Thus giving the required result. 

**PROOF of Lemma 3.2** The proof of (i) follows immediately from $L(\omega)f(u;\omega)L(\omega) \in L_2(\mathbb{R}^{d \times d})$.

To prove (ii), we note that if $\{X_\epsilon\}$ is second order stationary, then $f(u;\omega) = f(\omega)$. Therefore, $L(\omega)f(u;\omega)L(\omega) = I_d$ and $\mathbf{A}(r,\ell) = 0$ for all $r$ and $\ell$, except $\mathbf{A}(0,0) = I_d$. To prove the only if part, suppose $\mathbf{A}(r,\ell) = 0$ for all $r \neq 0$ and all $\ell \in \mathbb{Z}$ then $\sum_{r,\ell} \mathbf{A}(r,\ell) \exp(-2\pi i r u) \exp(-i\lambda \omega)$ is only a function of $\omega$, thus $f(u;\omega)$ is only a function of $\omega$ which immediately implies that the underlying process is second order stationary.

To prove (iii) we use integration by parts. Under Assumption 3.2(L2, L4) the first derivative of $f(u;\omega)$ exists with respect to $u$ and the second derivative exists with respect to $\omega$ (moreover with respect to $\omega$ $L(\omega)f(u;\omega)L(\omega)$ is a periodic continuous function). Therefore by integration by parts, twice with respect to $\omega$ (using that $G(u;0) = G(u;2\pi)$ and $\frac{\partial G(u;0)}{\partial \omega} = \frac{\partial G(u;2\pi)}{\partial \omega}$, where $G(u;\omega) = L(\omega)f(u;\omega)L(\omega)$) and once
Thus we have proven the lemma. \[\square\]

Suppose us to show asymptotic normality of \(\tilde{C}_T(r, \ell)\). In Lemmas A.12 and A.13 we will show that the inner sum decays sufficiently fast over \((t, \tau, \ell)\) to allow us to show asymptotic normality of \(\tilde{c}_{j_1,j_2}(r, \ell)\) and \(\mathcal{S}_T(r, \ell)\).

### A.4 Proof of Theorems 3.3 and 3.6

The objective in this section is to prove asymptotic normality of \(\tilde{C}_T(r, \ell)\). We start by studying its approximation \(\tilde{c}_{j_1,j_2}(r, \ell)\), which we use to show asymptotic normality. Expanding \(\tilde{c}_{j_1,j_2}(r, \ell)\) gives the quadratic form

\[
\tilde{c}_{j_1,j_2}(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} \mathcal{L}_{j_1,k} \cdot (\omega_k + r) \mathcal{L}_{j_2,k} \cdot (\omega_k + r) \exp(i \omega_k)
\]

In Lemmas A.12 and A.13 we will show that the inner sum decays sufficiently fast over \((t, \tau, \ell)\) to allow us to show asymptotic normality of \(\tilde{c}_{j_1,j_2}(r, \ell)\) and \(\mathcal{S}_T(r, \ell)\).

#### Lemma A.12

Suppose \(f(\omega)\) is a non-singular matrix and the second derivatives of the elements of \(f(\omega)\) with respect to \(\omega\) are bounded. Then, for all \(j_1, s_1, j_2, s_2 = 1, \ldots, d\), we have

\[
\sup_{z, \omega \in [0, 2\pi]} \left| \frac{\partial^2 \left( L_{j_1,s_1} \cdot [f(\omega)] L_{j_2,s_2} \cdot [f(\omega + z)] \right)}{\partial \omega^2} \right| < \infty \quad (A.26)
\]
and

\[ \sup_z |a_j(\nu; z)| \leq \frac{C}{|\nu|^2} \quad \text{and} \quad \sup_z |d_j(\nu; z)|_1 \leq \frac{C}{|\nu|^2} \quad \text{for } \nu \neq 0, \]  

(A.27)

where \( j = (j_1, s_1, j_2, s_2) \) and

\[ a_j(\nu; z) = \int_0^{2\pi} L_{j_1, s_1}(f(\omega)) L_{j_2, s_2}(f(\omega + z)) \exp(-i\nu \omega) d\omega, \]

\[ d_j(\nu; z) = \int_0^{2\pi} h_{s_1, s_2}(\nu; r) \nabla f(\omega) L_{j_1, s_1}(f(\omega)) L_{j_2, s_2}(f(\omega + z)) \exp(-i\nu \omega) d\omega. \]

(A.28)

and \( h_{s_1, s_2}(\nu; r) = \int_0^1 f_{s_1, s_2}(u; \omega) \exp(2\pi i u r) du \) with a finite constant \( C \).

**PROOF.** Implicit differentiation of \( \partial L_{js}(f(\omega)) \) and implicit differentiation together with the product rule of \( \frac{\partial^2 L_{js}(f(\omega))}{\partial \omega^2} \) gives

\[ \frac{\partial L_{js}(f(\omega))}{\partial \omega} = \frac{\partial f(\omega)}{\partial \omega} \nabla f_{L_{js}}(f(\omega)) \quad \text{and} \]

\[ \frac{\partial^2 L_{js}(f(\omega))}{\partial \omega^2} = \frac{\partial^2 f(\omega)}{\partial \omega^2} \nabla^2 f_{L_{js}}(f(\omega)) + \frac{\partial^2 f(\omega)}{\partial \omega^2} \nabla^2 f_{L_{js}}(f(\omega)) \frac{\partial f(\omega)}{\partial \omega}. \]  

(A.29)

By using Lemma A.1, we have \( \sup_{\omega} |\nabla f_{L_{js}}(f(\omega))| < \infty \) and \( \sup_{\omega} |\nabla^2 f_{L_{js}}(f(\omega))| < \infty \). Since \( \sum_h h^2 |\kappa(h)|_1 < \infty \) (or equivalently in the nonstationary case, the integrated covariance satisfies this assumption), then we have \( |\frac{\partial f(\omega)}{\partial \omega}|_1 < \infty \) and \( |\frac{\partial^2 f(\omega)}{\partial \omega^2}|_1 < \infty \). Substituting these bounds into (A.29) gives (A.26).

To prove \( \sup_z |a_j(\nu; z)| \leq C|\nu|^{-2} \) (for \( \nu \neq 0 \)), we use (A.26) and apply integration by parts twice to \( a_j(\nu; z) \) to obtain the bound (similar to the proof of Lemma 3.1, in Appendix A.3). We use the same method to obtain bounds on \( G_{\omega_1}(\nu) \) for \( \nu \neq 0 \). \( \square \)

**Lemma A.13** Suppose that either Assumption 3.1(P1, P3, P4) or Assumption 3.2 (L1, L2, L3) holds (in the stationary case let \( \Sigma = \Sigma_{s,T} \)). Then we have

\[ \tilde{c}_{j_1, j_2}(r, \ell) = \frac{1}{T} \sum_{t=1}^{T} X_t G_{\omega_t}(t - \tau - \ell) \exp(i\tau \omega_t) + O_p \left( \frac{1}{T} \right), \]

where \( G_{\omega_1}(\nu) = \int_0^{2\pi} L_{j_2, 1}(\omega + \omega_r) L_{j_1, 1}(\omega) \exp(-i\nu \omega) d\omega = \{a_{j_1, s_1, j_2, s_2}(\nu; \omega_r); 1 \leq s_1, s_2 \leq d\}, |G_{\omega_1}(\nu)|_1 \leq C|\nu|^2. \)

**PROOF.** We replace \( \frac{1}{T} \sum_{t=1}^{T} L_{j_2, 1}(\omega_{k+t}) L_{j_1, 1}(\omega_{k}) \exp(-i\omega_{k}(t - \tau - \ell)) \) in (A.25) with its integral limit \( G_{\omega_1}(t - \tau + \ell) \), and by using (A.27), we obtain bounds on \( G_{\omega_1}(s) \). This gives the required result. \( \square \)
Theorem A.2 Suppose that \( \{X_t\}_t \) satisfies Assumption 3.1(P1-P3). Then for all fixed \( r \in \mathbb{N} \) and \( \ell \in \mathbb{Z} \), we have
\[
\sqrt{T} \text{vech}\left( \mathbb{R} \tilde{C}_T(r, \ell) \right) \overset{D}{\to} \mathcal{N}\left( \mathbb{0}_{d(d+1)/2}, \mathbf{W}_{\ell,\ell} \right)
\]
and
\[
\sqrt{T} \text{vech}\left( \mathbb{I} \tilde{C}_T(r, \ell) \right) \overset{D}{\to} \mathcal{N}\left( \mathbb{0}_{d(d+1)/2}, \mathbf{W}_{\ell,\ell} \right),
\]
where \( \mathbb{0}_{d(d+1)/2} \) is the \( d(d+1)/2 \) zero vector and \( \mathbf{W}_{\ell,\ell} = \mathbf{W}^{(1)}_{\ell} + \mathbf{W}^{(2)}_{\ell,\ell} \) as defined in (2.13) and (2.17).

PROOF. Since each element of \( \tilde{C}_T(r, \ell) \) can be approximated by the quadratic form given in Lemma A.13, to show asymptotic normality of \( \tilde{C}_T(r, \ell) \), we use a central limit theorem for quadratic forms. One such central limit theorems is given in Lee and Subba Rao (2011), Corollary 2.2 (which holds for both stationary and nonstationary time series). Assumption 3.1 (P1-P3) implies the conditions in Lee and Subba Rao (2011), Corollary 2.2 as satisfied, therefore using \( \mathbb{R}Z = \frac{1}{2}(Z + Z) \), \( \mathbb{I}Z = \frac{1}{2i}(Z - Z) \) and Cramer-Wold device, we get asymptotic normality of \( \sqrt{T} \text{vech}\left( \mathbb{R} \tilde{C}_T(r, \ell) \right) \) and \( \sqrt{T} \text{vech}\left( \mathbb{I} \tilde{C}_T(r, \ell) \right) \).  

PROOF of Theorem 3.3 Since \( \sqrt{T} \hat{C}_T(r, \ell) = \sqrt{T} \tilde{C}_T(r, \ell) + o_p(1) \), to show asymptotic normality of \( \sqrt{T} \hat{C}_T(r, \ell) \), we are only required to show asymptotic normality of \( \sqrt{T} \tilde{C}_T(r, \ell) \). Asymptotic normality of \( \sqrt{T} \tilde{C}_T(r, \ell) \) follows immediately from Theorem A.2 and, similarly, by the Cramer-Wold device, we can show the desired joint normality result.

PROOF of Theorem 3.4 Follows immediately from Theorem 3.3.

We now derive the distribution of \( \hat{C}(r, \ell) \) under the assumption of local stationarity. We recall from Theorem 3.5 that the distribution of \( \tilde{C}_T(r, \ell) \) is determined by \( \tilde{C}_T(r, \ell) \) and \( S_T(r, \ell) \). We have shown in Lemma A.13 that \( \tilde{C}_T(r, \ell) \) can be approximated by a quadratic form. We now show that \( S_T(r, \ell) \) is also a quadratic form. Substituting the quadratic form expansion
\[
\hat{f}_{k,r} - \mathbb{E}(\hat{f}_{k,r}) = \frac{1}{2\pi T} \sum_{t, \tau=1}^{T} \lambda_0(t - \tau) \mathbf{g}(X_t X'_{\tau}) \exp(-i(t - \tau)\omega_k),
\]
where the random vector \( \mathbf{g}(X_t X'_{\tau}) \) is defined as
\[
\mathbf{g}(X_t X'_{\tau}) = \left( \begin{array}{c} 1 \\ \exp(-i(t - \tau)\omega_r) \end{array} \right) \otimes \left[ \text{vec}(X_t X'_{\tau}) - \mathbb{E}(\text{vec}(X_t X'_{\tau})) \right],
\]
we have
into $S_{T,j_1,j_2}(r,\ell)$ (defined in (A.8)) together with Lemma A.8 and A.12 gives
\[
S_{T,j_1,j_2}(r,\ell) = \frac{1}{T} \sum_{k=1}^{T} \sum_{s_1,s_2=1}^{d} E(J_{k,s_1}J_{k+r,s_2}) (f_{k,r} - E(f_{k,r}))' \nabla A_{j_1,s_1,j_2,s_2}(f_{k,r}) e^{i\ell\omega_k}
\]
\[
= \sum_{s_1,s_2=1}^{d} \frac{1}{2\pi T} \sum_{t,\tau=1}^{T} \lambda_b(t-\tau) g(X_tX_{\tau}') \frac{1}{T} \sum_{k=1}^{T} \exp(-i(t-\tau-\ell)\omega_k) h_{s_1,s_2}(\omega_k;r) \nabla A_{j_1,s_1,j_2,s_2}(f_{k,r}) + O\left(\frac{1}{T}\right)
\]
\[
= \sum_{s_1,s_2=1}^{d} \frac{1}{2\pi T} \sum_{t,\tau=1}^{T} \lambda_b(t-\tau) g(X_tX_{\tau}') \widetilde{d}_{j_1,s_1,j_2,s_2}(t-\tau-\ell;\omega_{\tau}) + O\left(\frac{1}{T}\right)
\]
(A.31)

where $d_{j_1,s_1,j_2,s_2}(t-\tau-\ell;\omega_{\tau})$ is defined in (A.28).

**PROOF of Theorem 3.6** Theorem 3.5 implies that
\[
\tilde{c}_{j_1,j_2}(r,\ell) - B_{T,j_1,j_2}(r,\ell) = \tilde{c}_{j_1,j_2}(r,\ell) + S_{T,j_1,j_2}(r,\ell) + o_p\left(\frac{1}{\sqrt{T}}\right).
\]
By using Lemma A.13 and (A.31), we have that $\tilde{c}_{j_1,j_2}(r,\ell) + S_{T,j_1,j_2}(r,\ell)$ is a quadratic form. Therefore, by applying Lee and Subba Rao (2011), Corollary 2.2 to $\tilde{c}_{j_1,j_2}(r,\ell) + S_{T,j_1,j_2}(r,\ell)$, we can prove (3.11). $\square$

**A.5 Proof of results in Section 4**

**PROOF of Lemma 4.1.** We first prove (i). Politis and Romano (1994) have shown that the stationary bootstrap leads to a bootstrap sample which is stationary conditional on the observations $\{X_t\}_{t=1}^{T}$. Therefore, by using the same arguments, as those used to prove Lemma 1 in Politis and Romano (1994), and conditioning on the first block length $L_1$ for $0 \leq t_1 \leq t_2 \ldots \leq t_{n-1}$, we have
\[
cum^*(X_1^r, X_1+t_1 \ldots, X_1+t_{n-1}) = cum^*(X_1^r, X_1+t_1, \ldots, X_1+t_{n-1} | L_1 > t_{n-1}) P(L_1 > t_{n-1})
\]
\[
+ cum^*(X_1^r, X_1+t_1, \ldots, X_1+t_{n-1} | L_1 \leq t_{n-1}) P(L_1 \leq t_{n-1}).
\]
We observe that $cum^*(X_1^r, X_1+t_1, \ldots, X_1+t_{n-1} | L_1 \leq t_{n-1}) = 0$ (since the random variables in separate blocks are conditionally independent), $cum^*(X_1^r, X_1+t_1, \ldots, X_1+t_{n-1} | L_1 > t_{n-1}) = \tilde{\rho}_n^C(t_1, \ldots, t_{n-1})$ and $P(L_1 > t_{n-1}) = (1-p)^{n-1}$. Thus altogether, we have $cum^*(X_1^r, X_1^*, \ldots, X_1^{*n-1}) = (1-p)^{n-1} \tilde{\rho}_n^C(t_1, \ldots, t_{n-1})$.

We now prove (ii). We first bound the difference $\hat{\mu}_n^C(h_1, \ldots, h_{n-1}) - \hat{\mu}_n(h_1, \ldots, h_{n-1})$. Without loss of generality, we consider the case $1 \leq h_1 \leq h_2 \cdots \leq h_{n-1} < T$. Comparing $\hat{\mu}_n^C$ with $\hat{\mu}_n$, we observe that the only difference is that $\hat{\mu}_n^C$ contains a few additional terms due to $Y_t$ for $t > T$, therefore
\[
\hat{\mu}_n^C(h_1, \ldots, h_{n-1}) - \hat{\mu}_n(h_1, \ldots, h_{n-1}) = \frac{1}{T} \sum_{t=T-h_{n-1}+1}^{T} Y_t \prod_{i=1}^{n-1} Y_{t+h_i}.
\]

64
Since $Y_t = X_{(t-1) \mod T+1}$, we have
\[
\| \hat{\mu}_n(h_1, \ldots, h_{n-1}) - \hat{\mu}_n(h_1, \ldots, h_{n-1}) \|_{q/n} \leq \frac{h_{n-1}}{T} \sup_t \| X_t \|_q^n
\]
and substituting this bound into (4.2) gives (ii).

We partition the proof of (iii) in two stages. First, we derive the sampling properties of the sample moments, then using these results we derive the sampling properties of the sample cumulants. We assume $0 \leq h_1 \leq \ldots \leq h_{n-1}$, and define the product $Z_t = X_t \prod_{i=1}^{n-1} X_{t+h_i}$ and the sigma-algebra $\mathcal{F}_t = \sigma(X_t, X_{t+h_1}, \ldots)$. By using Ibragimov's inequality, we have $\| E(Z_t | \mathcal{F}_{t-i}) - E(Z_t | \mathcal{F}_{t-i-1}) \|_m \leq C \| Z_t \|_r |i|^{-\alpha(1-\frac{1}{m})}$. Let $M_i(t) = E(Z_t | \mathcal{F}_{t-i}) - E(Z_t | \mathcal{F}_{t-i-1})$, then we have the representation $Z_t = E(Z_t) = \sum_i M_i(t)$. Using the above and applying Burkholder's inequality (in the case that $m \geq 2$), to the last line below, we obtain the bound
\[
\| \hat{\mu}_n(h_1, \ldots, h_{n-1}) - E(\hat{\mu}_n(h_1, \ldots, h_{n-1})) \|_m \\
\leq \frac{1}{T} \sum_{t=1}^{T} \left( \prod_{i=1}^{n-1} X_{t+h_i} - E(X_t \prod_{i=1}^{n-1} X_{t+h_i}) \right) \|_m \\
\leq \frac{1}{T} \sum_{t=1}^{T} \left( \sum_i M_i(t) \right) \|_m \leq \frac{1}{T} \sup_t \| Z_t \|_r \sum_i |i|^{-\alpha(1-\frac{1}{m})}
\]
which is of order $O(T^{-1/2})$ if for some $r > m\alpha/(\alpha - m)$ we have $\sup_t \| Z_t \|_r < \infty$. Next we write these conditions in the terms of the moments of $X_t$. Since $\sup_t \| Z_t \|_r \leq (\sup_t \| X_t \|_r)^n$, if $\alpha > m$ and $r$ such that $\sup_t \| X_t \|_r < \infty$ where $r > nm\alpha/(\alpha - m)$, then $\| \hat{\mu}_n(h_1, \ldots, h_{n-1}) - E(\hat{\mu}_n(h_1, \ldots, h_{n-1})) \|_m = O(T^{-1/2})$. As the sample cumulant is a sum of products of sample moments, we use the above to bound products of sample moments (extracted from the nth order cumulant in (4.3)). By the (generalized) Hölder inequality, we get
\[
\left\| \prod_{B \in \pi} \hat{\mu}_{|B|}(B) - \prod_{B \in \pi} E[\hat{\mu}_{|B|}(B)] \right\|_{q/n} \\
\leq \sum_{j=1}^{\lfloor n \rfloor} \left\| \hat{\mu}_{|B_j|}(B_j) - E[\hat{\mu}_{|B_j|}(B_j)] \right\|_{qD_j/(n|B_j|)} \left( \prod_{k=1}^{j-1} \left\| \hat{\mu}_{|B_k|}(B_k) \right\|_{qD_j/(n|B_k|)} \right) \prod_{k=j+1}^{\lfloor n \rfloor} E[\hat{\mu}_{|B_k|}(B_k)]
\]
where $\pi = \{B_1, \ldots, B_{\lfloor n \rfloor}\}$ and $D_j = \sum_{k=1}^{\lfloor n \rfloor} |B_k|$ (noting that $D_{|\pi|} = \sum_{k=1}^{\lfloor n \rfloor} |B_k| = n$). Applying the previous discussion to this situation (with $n = |B_j|$ and $m = \frac{qD_j}{n|B_j|} = q/|B_j|$), we see that to ensure $O(T^{-1/2})$ convergence of the above expression we require that the mixing rate should satisfy $\alpha > \frac{\alpha}{|B_j|}$ and
\[
r > \frac{|B_j| q\alpha/|B_j|}{\alpha - \frac{q}{|B_j|}} = \frac{q\alpha}{\alpha - q/|B_j|} \quad \text{for all } j.
\]
Noting that $1 \leq |B_j| \leq n$, the minimum conditions for the above to be true for all partitions $\pi \in$
\[ \{h_1, \ldots, h_{n-1}\} \text{ is } \alpha > q \text{ and } \|X_t\|_r < \infty \text{ for } r > q\alpha/(\alpha - q/n). \] Altogether this gives

\[ \|\tilde{\kappa}_n(h_1, \ldots, h_{n-1}) - \kappa_n(h_1, \ldots, h_{n-1})\|_{q/n} \leq \sum_{\pi} (|\pi| - 1)! \left\| \prod_{B \in \pi} \hat{\mu}_{\pi[B]}(B) - \prod_{B \in \pi} E[\hat{\mu}_{\pi[B]}(B)] \right\|_{q/n} = O\left(\frac{1}{T^{1/2}}\right) \]

(under the condition \(\alpha > q\) and \(\|X_t\|_r < \infty\) for \(r > q\alpha/(\alpha - q/n)\)). This proves (4.6).

We now prove (4.7). It is straightforward to show that if \(0 \leq h_1 \leq \ldots \leq h_{n-1} \leq T\), then we have

\[ \frac{1}{T} \sum_{t=1}^{T-h_{n-1}} E(X_t X_{t+h_1} \ldots X_{t+h_{n-1}}) - \frac{1}{T} \sum_{t=1}^{T} E(X_t X_{t+h_1} \ldots X_{t+h_{n-1}}) \leq C \frac{h_{n-1}}{T}. \]

Using this and the same methods as above we have (4.7) thus we have shown (iii).

To prove (iv), we note that it is immediately clear that \(\tilde{\kappa}_n(\cdot)\) is the nth order cumulant of a stationary time series. However, in the case that the time series is nonstationary, the story is different. To prove (iva), we note that under the assumption that \(E(X_t)\) is constant for all \(t\), we have

\[ \tilde{\kappa}_2(h) = \frac{1}{T} \sum_{t=1}^{T} E(X_t X_{t+h}) - \left(\frac{1}{T} \sum_{t=1}^{T} E(X_t)\right)^2 \]

\[ = \frac{1}{T} \sum_{t=1}^{T} E((X_t - \mu)(X_{t+h} - \mu)) \quad \text{(using } E(X_t) = \mu\text{)} \]

\[ = \frac{1}{T} \sum_{t=1}^{T} \text{cov}(X_t, X_{t+h}). \]

To prove (ivb), we note that by using the same argument as above, we have

\[ \tilde{\kappa}_3(h_1, h_2) = \frac{1}{T} \sum_{t=1}^{T} E(X_t X_{t+h_1} X_{t+h_2}) - \left(\frac{1}{T} \sum_{t=1}^{T} E(X_t X_{t+h_1}) + E(X_{t+h_1} X_{t+h_2}) + E(X_t X_{t+h_2})\right)\mu + 2\mu^3 \]

\[ = \frac{1}{T} \sum_{t=1}^{T} E((X_t - \mu)(X_{t+h_1} - \mu)(X_{t+h_2} - \mu)) = \frac{1}{T} \sum_{t=1}^{T} \text{cum}(X_t, X_{t+h_1}, X_{t+h_2}), \]

which proves (ivb).

So far, the above results give the average cumulants. However, this pattern does not continue for \(n \geq 4\). We observe that

\[ \tilde{\kappa}_4(h_1, h_2, h_3) = \frac{1}{T} \sum_{t=1}^{T} E[(X_t - \mu)(X_{t+h_1} - \mu)(X_{t+h_2} - \mu)(X_{t+h_2} - \mu)] - \]

\[ \left(\frac{1}{T} \sum_{t=1}^{T} \text{cov}(X_t, X_{t+h_1})\right)\left(\frac{1}{T} \sum_{t=1}^{T} \text{cov}(X_{t+h_2}, X_{t+h_3})\right) - \left(\frac{1}{T} \sum_{t=1}^{T} \text{cov}(X_t, X_{t+h_2})\right) \times \]

\[ \left(\frac{1}{T} \sum_{t=1}^{T} \text{cov}(X_{t+h_1}, X_{t+h_3})\right) - \left(\frac{1}{T} \sum_{t=1}^{T} \text{cov}(X_t, X_{t+h_3})\right)\left(\frac{1}{T} \sum_{t=1}^{T} \text{cov}(X_{t+h_1}, X_{t+h_2})\right), \]
which cannot be written as the average of the fourth order cumulant. However, it is straightforward to show that the above can be written as the average of the fourth order cumulants plus the additional average covariances. This proves \(\text{(ivc)}\). The proof for \(\text{(ivd)}\) is similar and we omit the details. \(\square\)

**PROOF of Lemma 4.2.** To prove \(\text{(i)}\), we use the triangle inequality to obtain

\[
|\hat{h}_n(\omega_1, \ldots, \omega_{n-1}) - f_{n,T}(\omega_1, \ldots, \omega_{n-1})| \leq I + II,
\]

where

\[
I = \frac{1}{(2\pi)^{n-1}} \sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{\max(h_1, 0) - \min(h_1, 0)} [\tilde{\kappa}_n(h_1, \ldots, h_{n-1}) - \widetilde{\kappa}_n(h_1, \ldots, h_{n-1})],
\]

\[
II = \frac{1}{(2\pi)^{n-1}} \sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{\max(h_1, 0) - \min(h_1, 0)} [\tilde{\kappa}_n(h_1, \ldots, h_{n-1}) - \pi_n(h_1, \ldots, h_{n-1})].
\]

We first bound the sum \(\sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{\max(h_1, 0) - \min(h_1, 0)}\). There are \(n-1\)! orderings of \(\{h_1, \ldots, h_{n-1}\}\), thus we have the bound

\[
\sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{\max(h_1, 0) - \min(h_1, 0)} \leq (n-1)!
\]

\[
\sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{\max(h_1, 0) - \min(h_1, 0)}.
\]

Therefore we need only consider the sum when \(h_1 \leq h_2 \leq \ldots \leq h_{n-1}\). This sum can be further partitioned into \(n\) cases

\[
\sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{\max(h_{n-1}, 0) - \min(h_1, 0)} = \sum_{m=0}^{n-1} I_m
\]

where

\[
I_0 = \sum_{h_1 \leq h_2 \leq \ldots \leq h_{n-1}} (1 - p)^{h_{n-1}}, \quad I_{n-1} = \sum_{h_1 \leq h_2 \leq \ldots \leq h_{n-1}} (1 - p)^{-h_1}
\]

and for \(1 \leq m < n - 1\)

\[
I_m = \sum_{h_1 \leq h_2 \leq \ldots \leq h_{n-1}} (1 - p)^{h_{n-1} - h_1},
\]

To bound \(I_0\) we use that

\[
I_0 = \sum_{h_1 \leq h_2 \leq \ldots \leq h_{n-1}} (1 - p)^{\sum_{i=1}^{n-1} (h_i - h_{i-1})}
\]
where $h_0 = 0$. By making a change of variables, with $g_1 = h_1$, $g_2 = h_2 - h_1$, $g_{n-1} = h_{n-1} - h_{n-2}$ we obtain $I_1 \leq \sum_{g=1}^{\infty} (1 - p)^{g} 1^{n-1} = p^{1-n}$. To bound $I_m$ (where $1 \leq m < n - 1$) we split the sum into negative and positive indices

$$I_m = \left( \sum_{h_1 \leq h_2 \leq \ldots \leq h_m < 0} (1 - p)^{-h_1} \right) \times \left( \sum_{0 \leq h_{m+1} \leq h_{m+2} \leq \ldots \leq h_{n-1}} (1 - p)^{h_{n-1}} \right).$$

By applying the same argument to bound $I_0$ to each of the sums above we obtain $I_m \leq p^{1-n}$. Finally, noting that $I_0 = I_{n-1}$ we obtain $I_{n-1} \leq p^{1-n}$. Altogether this gives

$$\sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{\max(h_i, 0) - \min(h_i, 0)} \leq (n-1)! np^{1-n} = n! p^{1-n}. \quad \text{(A.33)}$$

Therefore, by using (4.6) and (A.33), we have

$$\|I\|_{q/n} \leq \frac{1}{(2\pi)^{n-1}} \sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{\max(h_i, 0) - \min(h_i, 0)} \|\tilde{\kappa}_n(h_1, \ldots, h_{n-1}) - \tilde{\kappa}_n(h_1, \ldots, h_{n-1})\|_{q/n} \leq O(T^{-1/2}) \text{ (uniform in } h_i \text{) by eq. (4.6)}$$

To bound $II$ we use (4.7) to give

$$|II| \leq C \sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{\max(h_i, 0) - \min(h_i, 0)} (\max(h_i, 0) - \min(h_i, 0)).$$

By using the same decomposition of the integral used to bound (A.33), together with the bound

$$\sum_{0 \leq h_1 \leq \ldots \leq h_{n-1}} h_{n-1}(1 - p)^{h_{n-1}} \leq \sum_{h=0}^{\infty} h^{n-1}(1 - p)^{h} \leq Cp^{-n},$$

(where $C$ is a finite constant) we obtain

$$\sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{\max(h_i, 0) - \min(h_i, 0)} (\max(h_i, 0) - \min(h_i, 0)) \leq C n! p^{-n}.$$  

Thus $|II| = O(T^{-n/2})$. This proves (i).

To prove (ii), we note that

$$|\tilde{\kappa}_n(\omega_1, \ldots, \omega_{n-1}) - f_n(\omega_1, \ldots, \omega_{n-1})| \leq |\tilde{\kappa}_n(\omega_1, \ldots, \omega_{n-1}) - f_{n,T}(\omega_1, \ldots, \omega_{n-1})| + |f_{n,T}(\omega_1, \ldots, \omega_{n-1}) - f_n(\omega_1, \ldots, \omega_{n-1})|.$$

A bound for the first term on the right hand side of the above is given in part (i). To bound the second term, we note that $\tilde{\kappa}_n(\cdot) = \kappa_n(\cdot)$ (where $\kappa_n(\cdot)$ are the cumulants of an nth order stationary time series). Using this leads to the triangle inequality

$$|f_{n,T}(\omega_1, \ldots, \omega_{n-1}) - f_n(\omega_1, \ldots, \omega_{n-1})| \leq III + IV$$
\[ III = \frac{1}{(2\pi)^{n-1}} \sum_{h_1, \ldots, h_{n-1} \in \mathbb{Z}^{n-1}} (1 - p)^{\max(h_i,0) - \min(h_i,0)} - 1 \cdot |\kappa_n(h_1, \ldots, h_{n-1})|, \]

\[ IV = \frac{1}{(2\pi)^{n-1}} \sum_{\max(h_i,0) - \min(h_i,0) \geq T} |\kappa_n(h_1, \ldots, h_{n-1})|. \]

Substituting the bound \(|1 - (1-p)^i| \leq Kip\), into III gives \(III = O(p)\). To bound IV, we will use that under the assumption that \(\alpha > 2r(n-1)/(r-n)\) and using Lemma A.9 for \(0 < h_1 < \ldots < h_{n-1}\) we have that \(\kappa_n(h_1, \ldots, h_{n-1}) \leq C \prod_{i=1}^{n-1} (h_i - h_{i-1})^{-2}\) (where we set \(h_0 = 0\)) and for \(h_1 < h_2 < \ldots < h_m < 0 < h_{m+1} < \ldots < h_{n-1}\) we have that \(\kappa_n(h_1, \ldots, h_{n-1}) \leq C(-h_m)^{-2}h_{m+1}^{-2} \prod_{i=m+1}^{n-1} (h_i - h_{i-1})^{-2}\) (the case that \(h_i = h_{i+1}\) is similarly defined, where we set \((h_i - h_{i-1})^{-2} = C\)). This is now used to bound IV. As in the bound of I (above) we can show that

\[ IV \leq \frac{(n-1)!}{(2\pi)^{n-1}} \sum_{h_1 \leq h_2 \leq \ldots \leq h_{n-1}} |\kappa_n(h_1, \ldots, h_{n-1})| = \sum_{m=0}^{n-1} IV_m, \]

where

\[ IV_0 = \frac{(n-1)!}{(2\pi)^{n-1}} \sum_{h_1 \leq h_2 \leq \ldots \leq h_{n-1}} |\kappa_n(h_1, \ldots, h_{n-1})| \]

\[ IV_m = \frac{(n-1)!}{(2\pi)^{n-1}} \sum_{h_1 \leq h_2 \leq \ldots \leq h_{n-1}} |\kappa_n(h_1, \ldots, h_{n-1})| \quad 1 \leq m \leq n-2, \]

\[ IV_{n-1} = \frac{(n-1)!}{(2\pi)^{n-1}} \sum_{h_1 \leq h_2 \leq \ldots \leq h_{n-1}} |\kappa_n(h_1, \ldots, h_{n-1})| \]

We first bound \(IV_0\). By definition of \(IV_0\), \(h_{n-1} \geq T\), this means that for at least one \(1 \leq i \leq n-1\) we have \((h_i - h_{i-1}) \geq T/(n-1)\). Therefore, by using the bound \(\kappa_n(h_1, \ldots, h_{n-1}) \leq C \prod_{i=1}^{n-1} (h_i - h_{i-1})^{-2}\), this gives \(IV_0 \leq C(T/n)^{-1}\) (where \(C\) is a finite constant that only depends on \(n\)). The same argument can be used to show \(IV_m \leq C(T/n)^{-1}\) for \(1 \leq m \leq n-1\). Altogether this gives

\[ |IV| \leq \frac{Cn \times n!}{T}, \]

and the bounds for III and IV give (ii).

We now prove (iii). In the case that \(n \in \{2,3\}\), the proof is identical to the stationary case since \(\hat{h}_2\) and \(\hat{h}_3\) are estimators of \(f_{2,T}\) and \(f_{3,T}\), which are the Fourier transforms of average covariances and average cumulants. Since the second and third order covariances decay at a sufficiently fast rate, \(f_{2,T}\) and \(f_{3,T}\) are finite. This proves (iii).
On the other hand, we will prove that for \( n \geq 4 \), \( f_{n,T} \) depends on \( p \). We prove the result for \( n = 4 \) (the result for the higher order cases follow similarly). Lemma A.9 implies that \( \sup_h \sum_{h} \left| \frac{1}{T} \sum_{t=1}^{T} \text{cov}(X_t, X_{t+h}) \right| < \infty \) and \( \sup_{h_1, h_2, h_3} \left| \frac{1}{T} \sum_{t=1}^{T} \text{cum}(X_t, X_{t+h_1}, X_{t+h_2}, X_{t+h_3}) \right| < \infty \). Therefore, taking absolutes inside the sum of \( f_{4,T}() \), using the \( h_1 \leq h_2 \leq \ldots \leq h_{n-1} \) decomposition given above and that \( \sup_{h_1, h_2} |\mathcal{K}_4(h_1, h_2, h_3)| < \infty \) (note the boundedness of (4.8) over the double (but not triple) sum) we get

\[
\sup_{\omega_1, \omega_2, \omega_3} |f_{4,T}(\omega_1, \omega_2, \omega_3)| \leq \frac{1}{(2\pi)^3} \sum_{h_1, h_2, h_3 = -(T-1)}^{T-1} (1 - p)^{\max(h_1,0) - \min(h_3,0)} |\mathcal{K}_4(h_1, h_2, h_3)| \leq C \sum_{h=1}^{T-1} (1 - p)^h = O(p^{-1}),
\]

where \( C \) is a finite constant (this proves (iii)). The proof for the bound of the higher order \( f_{n,T} \) is similar. Thus we have shown (iii). \( \square \)

**PROOF of Theorem 4.1.** Substituting Lemma 4.1(i) into \( \text{cum}^*(J^*_T(\omega_{k_1}), \ldots, J^*_T(\omega_{k_n})) \) gives

\[
\text{cum}^*(J^*_T(\omega_{k_1}), \ldots, J^*_T(\omega_{k_n})) = \frac{1}{(2\pi)^{n/2}} \sum_{t_1, \ldots, t_n = 1}^{T} (1 - p)^{\max_i((t_i - t_n),0) - \min_i((t_i - t_n),0)} \mathcal{K}_n^C(t_1 - t_n, \ldots, t_n - t_n) e^{-i\sum_{k=1}^{n} t_k \omega_{k_i}}.
\]

For \( 1 \leq i \leq n - 1 \) let \( h_i = t_i - t_n \) and \( t = t_n \), then the above can be written as

\[
\text{cum}^*(J^*_T(\omega_{k_1}), \ldots, J^*_T(\omega_{k_n})) = \frac{1}{(2\pi)^{n/2}} \sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{\max_i(h_i,0) - \min_i(h_i,0)} \mathcal{K}_n^C(h_1, \ldots, h_{n-1}) e^{-i\sum_{k=1}^{n-1} h_i \omega_{k_i}} \times \sum_{t = |\min_i(h_i,0)| + 1}^{T - |\max_i(h_i,0)|} e^{-i(t \omega_{k_1} + \omega_{k_2} + \ldots + \omega_{k_n})},
\]

where \( g(h) = \max_i(h_i,0) - \min_i(h_i,0) \). Using that \( \|\mathcal{K}_n^C(h_1, \ldots, h_{n-1})\|_1 < \infty \), it is clear from the above that \( \|\text{cum}^*(J^*_T(\omega_{k_1}), \ldots, J^*_T(\omega_{k_n}))\|_1 = O\left(\frac{1}{p^{n/2}}\right) \), which proves (4.13). However, this is a crude bound and below we obtain more precise bounds (under stronger conditions). Let

\[
E_h(\omega_{k_1}, \ldots, \omega_{k_n}) = \sum_{t = |\min_i(h_i,0)| + 1}^{T - |\max_i(h_i,0)|} e^{-i(t \omega_{k_1} + \omega_{k_2} + \ldots + \omega_{k_n})},
\]

Replacing \( \mathcal{K}_n^C(h_1, \ldots, h_{n-1}) \) in the above with \( \mathcal{K}_n(h_1, \ldots, h_{n-1}) \) gives

\[
\text{cum}^*(J^*_T(\omega_{k_1}), \ldots, J^*_T(\omega_{k_n})) = \frac{1}{(2\pi)^{n/2}} \sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{g(h)} \mathcal{K}_n(h_1, \ldots, h_{n-1}) e^{-i\sum_{k=1}^{n-1} h_i \omega_{k_i}} E_h(\omega_{k_1}, \ldots, \omega_{k_n}) \ (A.34)
\]
where

\[ R_1 = \frac{1}{(2\pi T)^{n/2}} \sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{g(h)} \left( \tilde{\kappa}_n(h_1, \ldots, h_{n-1}) - \tilde{\kappa}_n(h_1, \ldots, h_{n-1}) \right) E_h(\omega_1, \ldots, \omega_k). \]  

(A.35)

Substituting (4.5) into \( R_1 \) and using identical arguments to those used in the proof of Lemma 4.2 we have

\[
\|R_1\|_{q/n} \leq \frac{n! \sup \|X_t\|_q}{(2\pi T)^{n/2}} \sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{g(h)} \frac{g(h)}{T} |E_h(\omega_1, \ldots, \omega_k)| \leq (T-1) \max(h_1, 0) - \min(h_1, 0)) \]

\[
\leq \frac{n! \sup \|X_t\|_q}{(2\pi T)^{n/2}} \sum_{h_1, h_2 \leq \ldots \leq h_{n-1}}^{T-1} (1 - p)^{g(h)} g(h). \]

Just as the bound on \( I \) (in the proof of Lemma 4.2) we decompose the above sum into \( n \) sums where \( 0 \leq h_1 \leq \ldots \leq h_{n-1} \) using this decomposition and the same arguments as those used in Lemma 4.2 we have

\[
\|R_1\|_{q/n} = O\left(\frac{1}{(2\pi T)^{n/2}}\right). \]

We return to (A.34) and replace \( E_2(\omega_1, \ldots, \omega_k) \) with \( \sum_{t=1}^{T} e^{-it(\omega_1 + \omega_2 + \ldots + \omega_k)} \) to give

\[
\text{cum}^\tau(J_t^\tau(\omega_1), \ldots, J_t^\tau(\omega_k)) = \frac{1}{(2\pi T)^{n/2}} \sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{g(h)} \tilde{\kappa}_n(h_1, \ldots, h_{n-1}) e^{-ith \omega_1_1, \ldots, -ith \omega_{n-1}} \sum_{t=1}^{T} e^{-it(\omega_1 + \omega_2 + \ldots + \omega_k)} + R_1 + R_2, \]

(A.36)

where \( R_1 \) is defined in (A.35) and

\[
R_2 = \frac{1}{(2\pi T)^{n/2}} \sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{g(h)} \tilde{\kappa}_n(h_1, \ldots, h_{n-1}) \]

\[
\times e^{-ith_1 \omega_1_1, \ldots, -ith_{n-1} \omega_{n-1}} \left( T - \max(h_1, 0) \right) \sum_{t = \min(h_1, 0) + 1}^{T} e^{-it(\omega_1 + \omega_2 + \ldots + \omega_k)}. \]

(A.36) is in the form given in (4.14), with \( R_{T,n} = R_1 + R_2 \). To bound \( R_2 \) we take absolutes to give

\[
|R_2| \leq \frac{1}{(2\pi T)^{n/2}} \sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{g(h)} |\tilde{\kappa}_n(h_1, \ldots, h_{n-1})| (\max(h_i, 0) + \min(h_i, 0)). \]

By using Hölder’s inequality, it is straightforward to show that \( \|\tilde{\kappa}_n(h_1, \ldots, h_{n-1})\|_{q/n} \leq C < \infty. \) This
implies
\[ \|R_2\|_{q/n} \leq \frac{C}{(2\pi T)^{n/2}} \sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{g(h)} \max_i (|\max(h_i, 0)| + |\min(h_i, 0)|) \]
\[ \leq \frac{2C}{(2\pi T)^{n/2}} \sum_{h_1, \ldots, h_{n-1} = -(T-1)}^{T-1} (1 - p)^{g(h)} \max_i (|h_i|) = O\left(\frac{1}{T^{n/2}p^n}\right). \]

Therefore, since \(\|R_{T,n}\|_{q/n} \leq \|R_1\|_{q/n} + \|R_2\|_{q/n}\), we have \(\|R_{T,n}\|_{q/n} = O\left(\frac{1}{T^{n/2}p^n}\right)\). This proves (4.14).

To prove (a), we note that if \(\sum_{i=1}^{n} \omega_{k_i} \notin 2\pi \mathbb{Z}\), then the first term in (4.14) is zero and we have (4.15) (since \(R_{T,n} = O_p\left(\frac{1}{(T^{1/2}p^n)}\right)\)). On the other hand, if \(\sum_{i=1}^{n} \omega_{k_i} \in 2\pi \mathbb{Z}\), then the first term in (4.14) dominates and we use Lemma 4.2(ii) to obtain the other part of (4.15). The proof of (b) is similar, but uses Lemma 4.2(iii) rather than Lemma 4.2(ii), we omit the details. □

### A.6 Proofs for Section 5

**PROOF of Lemma 5.1.** We first note that by Assumption 5.1, we have summability of the 2nd to 8th order cumulants (see Lemma A.9 for details). Therefore, to prove (ia) we can use Theorem 4.1 to obtain

\[
\text{cum}^* (J^*_{T,j_1}(\omega_{k_1}), J^*_{T,j_2}(\omega_{k_2})) = f_{j_1,j_2}(\omega_{k_1}) \frac{1}{T} \sum_{t=1}^{T} \exp(-it(\omega_{k_1} + \omega_{k_2})) + O_p\left(\frac{1}{Tp^2}\right) = f_{j_1,j_2}(\omega_{k_1}) I(k_1 = -k_2) + O_p\left(\frac{1}{Tp^2}\right)
\]

The proof of (ib) and (ii) is identical, hence we omit the details. □

**PROOF of Theorem 5.1** Since the only random component in \(\hat{c}^*_j(r, \ell_1)\) are the DFTs, evaluating the covariance with respect to the bootstrap measure and using Lemma 5.2 to obtain an expression for the covariance between the DFTs gives

\[
T\text{cov}^* (\hat{c}^*_j, \hat{c}^*_j) (r, \ell_1) = \delta_{j_1,j_2} \delta_{j_1,j_3} \delta_{\ell_1,\ell_2} + \delta_{j_1,j_4} \delta_{j_2,j_3} \delta_{\ell_1,-\ell_2} + \kappa^{(r,\ell_1)}_j (j_1,j_2,j_3,j_4) + O_p\left(\frac{1}{Tp^4}\right)
\]

which gives both part (i) and (ii). □

The proof of the above theorem is based on \(\hat{c}^*_j(r, \ell)\) and we need to show that this is equivalent to \(\hat{c}^*_j(r, \ell)\) and \(\hat{c}^*_j(r, \ell)\), which requires the following lemma.

**Lemma A.14** Suppose \(\{X_t\}_t\) is a time series with a constant mean which satisfies Assumption 5.2(B2). Let \(\hat{F}_T^*\) be defined
in (2.22), and define \( \tilde{f}_{j_1j_2}^s(\omega_k) = f_{j_1j_2}^s(\omega_k) - E^*(\tilde{f}_{j_1j_2}^s(\omega_k)) \) and \( \tilde{I}_{k,r,j_1j_2}^* = I_{k,r,j_1j_2}^* - E^*(I_{k,r,j_1j_2}^*) \), where \( I_{k,r,j_1j_2}^* = J_{j_1j_2}^*(\omega_k)J_{j_2}^*(\omega_{k+r}) \). Then we have for all \( 1 \leq r < T/2 \)

\[
\|E^*|\tilde{f}_{j_1j_2}^s(\omega_k)|^2\|_4 = O\left( \frac{1}{bT} + \frac{1}{T^{3/2}p^3} + \frac{1}{T^2p^2b} \right),
\]

\[
\|\text{cum}_4^s(\tilde{f}_{j_1j_2}^s(\omega_k))\|_2 = O\left( \frac{1}{(bT)^3} + \frac{1}{(pT^{1/2})^4(bT)^2} + \frac{1}{(pT^{1/2})^6} \right),
\]

\[
\|E^*|\tilde{f}_{j_1j_2}^s(\omega_k)|^4\|_2 = O\left( \frac{1}{bT} + \frac{1}{T^{3/2}p^3} + \frac{1}{T^3p^2b} \right)^2,
\]

\[
\|E^*|J_{T,j_1}^*(\omega_k)\tilde{J}_{T,j_2}^*(\omega_{k+r})|\|_8 = O\left( 1 + \frac{1}{(pT^{1/2})^2} \right),
\]

\[
\|E^*|J_{T,j_1}^*(\omega_k)\tilde{J}_{T,j_2}^*(\omega_{k+r})|\|_8 = O\left( \frac{1}{(pT^{1/2})^2} \right),
\]

\[
\|\text{cov}^s(J_{T,j_1}^*(\omega_k)\tilde{J}_{T,j_2}^*(\omega_{k+r}),J_{T,j_3}^*(\omega_k)\tilde{J}_{T,j_4}^*(\omega_{s}))\|_4 = \begin{cases} O\left( \frac{1}{(pT^{1/2})^2} \right), & k = \pm s \text{ or } k = \pm(s + r) \\
O\left( \frac{1}{(pT^{1/2})^2} \right), & \text{otherwise}
\end{cases}
\]

\[
\|\text{cum}_3^s(J_{T,j_1}^*(\omega_k)\tilde{J}_{T,j_2}^*(\omega_{k+r}),J_{T,j_3}^*(\omega_k)\tilde{J}_{T,j_4}^*(\omega_{k+s}),\tilde{f}_{j_5j_6}^s(\omega_k))\|_{8/3} = \begin{cases} O\left( \frac{1}{bT(pT^{1/2})^2} + \frac{1}{(pT^{1/2})^3} \right), & k_1 = k_2 \text{ or } k_1 + r = k_2 \text{ or } k_1 = k_2 + r \\
O\left( \frac{1}{bT(pT^{1/2})^2} + \frac{1}{(pT^{1/2})^3} \right), & \text{otherwise}
\end{cases}
\]

\[
\|\text{cum}_2^s(J_{T,j_1}^*(\omega_k)\tilde{J}_{T,j_2}^*(\omega_{k+r}),J_{T,j_1}^*(\omega_k)\tilde{J}_{T,j_2}^*(\omega_{k+r}))\|_4 = \begin{cases} O(1), & k_1 = k_2 \text{ or } k_1 = k_2 + r \\
O\left( \frac{1}{(pT^{1/2})^3} \right), & \text{otherwise}
\end{cases}
\]

\[
\|\text{cum}_2^s(J_{T,j_1}^*(\omega_k)\tilde{J}_{T,j_2}^*(\omega_{k+r}),\tilde{f}_{j_3j_4}^s(\omega_k))\|_4 = O\left( \frac{1}{(pT^{1/2})^2(bT(pT^{1/2})^2)} \right),
\]

\[
\|E^*|\tilde{I}_{k_1r,j_1j_2}^s\tilde{I}_{k_2r,j_3j_4}^s(\omega_k)I_{j_3j_4}^*(\omega_{k_2})|\|_2 = \begin{cases} O\left( \frac{1}{bT} + \frac{1}{T^{3/2}p^3} + \frac{1}{T^3p^2b} \right), & k_1 = k_2 \text{ or } k_1 = k_2 + r \text{ or } k_2 = k_1 + r \\
O\left( \frac{1}{(pT^{1/2})^2} \right), & \text{otherwise}
\end{cases}
\]

and

\[
\|E^*|\tilde{f}_{j_1j_2}^s(\omega_k) - f_{j_1j_2}^s(\omega_k)|\|_8 = O\left( \frac{1}{pT^{1/2}} + p + b \right),
\]

with \( bT \rightarrow \) and \( p^{1/2}T \rightarrow \infty \) as \( T \rightarrow \infty \), \( b \rightarrow 0 \) and \( p \rightarrow 0 \). Note that all these bounds are uniform over frequency.
PROOF. Without loss of generality, we will prove the result in the univariate case (and under the assumption of nonstationarity). We will make wide use of (4.15) and (4.16) which we summarize below. For \( n \in \{2, 3\} \), we have

\[
\| \text{cum}^*(J_T^*(\omega_{k_1}), \ldots, J_T^*(\omega_{k_n})) \|_{q/n} = \begin{cases} 
O \left( \frac{1}{T^{n/2}} + \frac{1}{(pT^{1/2})^n} \right), & \sum_{l=1}^{n} \omega_{k_l} \in \mathbb{Z} \\
O \left( \frac{1}{(pT^{1/2})^n} \right), & \sum_{l=1}^{n} \omega_{k_l} \notin \mathbb{Z}
\end{cases}
\]

(A.48)

and, for \( n \geq 4 \),

\[
\| \text{cum}^*(J_T^*(\omega_{k_1}), \ldots, J_T^*(\omega_{k_n})) \|_{q/n} = \begin{cases} 
O \left( \frac{1}{T^{n/2}} + \frac{1}{(pT^{1/2})^n} \right), & \sum_{l=1}^{n} \omega_{k_l} \in \mathbb{Z} \\
O \left( \frac{1}{(pT^{1/2})^n} \right), & \sum_{l=1}^{n} \omega_{k_l} \notin \mathbb{Z}
\end{cases}
\]

To simplify notation, let \( J_T^*(\omega_k) = J_k^* \). To prove (A.37), we expand \( \mathbb{E}^*(\tilde{f}_{T}^{2}(\omega)) = \text{var}^*(\tilde{f}_{T}^{2}(\omega)) \) to give

\[
\| \text{var}^*(\tilde{f}_{T}^{2}(\omega)) \|_4 \leq \left\| \frac{1}{T^2} \sum_{l_1 \neq l_2} K_b(\omega_k - \omega_{l_1}) K_b(\omega_k - \omega_{l_2}) \text{cov}^*(J_{l_1}^*, J_{l_2}^*) \text{cov}^*(J_{l_1}^*, J_{l_2}^*) \right\|_4 \\
+ \left\| \frac{1}{T^2} \sum_{l_1 \neq -l_2} K_b(\omega_k - \omega_{l_1}) K_b(\omega_k - \omega_{l_2}) \text{cov}^*(J_{l_1}^*, J_{l_2}^*) \text{cov}^*(J_{l_1}^*, J_{l_2}^*) \right\|_4 \\
+ \left\| \frac{1}{T^2} \sum_{l_1 \neq l_2} K_b(\omega_k - \omega_{l_1}) K_b(\omega_k - \omega_{l_2}) \text{cum}^2(J_{l_1}^*, J_{l_2}^*, J_{l_1}^*, J_{l_2}^*) \right\|_4 \\
+ \left\| \frac{2}{T^2} \sum_{l} K_b(\omega_k - \omega_l)^2 |\text{cov}^*(J_{l}^*, J_{l}^*)|^2 \right\|_4 \\
\leq \frac{C}{T^2} \sum_{l_1 \neq l_2} K_b(\omega_k - \omega_{l_1}) K_b(\omega_k - \omega_{l_2}) \left( \frac{1}{(T^{1/2})^4} + \frac{1}{(pT^{1/2})^3} + \frac{1}{T} \right) \\
+ \frac{C}{T^2} \sum_{l} K_b(\omega_k - \omega_l)^2 \left( 1 + \frac{1}{(T^{1/2})^2} \right) \text{ (by using (A.48))} \\
= O \left( \frac{1}{T^{3/2}p^3} + \frac{1}{bT} + \frac{1}{bT(pT^{1/2})^2} \right) \text{ (these are just the leading terms)}.
\]

We now prove (A.38), expanding \( \text{cum}^*_4(\tilde{f}_{T}^{2}(\omega_k)) \) gives

\[
\| \text{cum}^*_4(\tilde{f}_{T}^{2}(\omega_k)) \|_2 = \left\| \frac{1}{T^2} \sum_{l_1 \neq l_2 \neq l_3 \neq l_4} \left( \prod_{i=1}^{4} K_b(\omega_k - \omega_{l_i}) \right) \text{cum}^*_4(|J_{l_1}^*|^2, |J_{l_2}^*|^2, |J_{l_3}^*|^2, |J_{l_4}^*|^2) \right\|_2.
\]

By using indecomposable partitions to decompose the cumulant \( \text{cum}^*_4(|J_{l_1}^*|^2, |J_{l_2}^*|^2, |J_{l_3}^*|^2, |J_{l_4}^*|^2) \) in terms of the product of cumulants of \( J_J \) and by (A.48), the leading term of \( \text{cum}^*_4(|J_{l_1}^*|^2, |J_{l_2}^*|^2, |J_{l_3}^*|^2, |J_{l_4}^*|^2) \) can be
shown to be the product of four covariances of the type $\text{cov}^*(J^*_{l_1}, J^*_{l_2}) \text{cov}^*(J^*_{l_3}, J^*_{l_0}) \text{cov}^*(\tilde{J}^*_{l_1}, J^*_{l_0})$. Using this and straightforward (but long) calculations we can show that

$$\|\text{cum}_3^*(\hat{f}_T^*(\omega_k))\|_2 = O\left(\frac{1}{(bT)^3} + \frac{1}{(pT)^{1/2}(bT)^2} + \frac{1}{(pT)^{1/2}(bT)^3} + \frac{1}{(pT)^{1/2}(bT)^4}\right),$$

which proves (A.38).

Since $E^*[\hat{f}_T^*(\omega)] = 0$, we have

$$E^*[\hat{f}_T^*(\omega_k)]^4 = 3\text{var}^*(\hat{f}_T^*(\omega_k))^2 + \text{cum}_3^*(\hat{f}_T^*(\omega_k)),$$

therefore by using (A.37) and (A.38), we obtain (A.39).

To prove (A.40), we note that $E^*[J^*_k \tilde{J}^*_k] \leq (E^*[J^*_k \tilde{J}^*_k])^2$, therefore by using (A.37) and (A.38), we obtain (A.39).

$$\|E^*[J^*_k \tilde{J}^*_k]\|_8 \leq \left(\|E^*[J^*_k \tilde{J}^*_k]\|_4^2 + \|E^*[J^*_k \tilde{J}^*_k]J^*_k\|_4^2 + \|E^*[J^*_k \tilde{J}^*_k]J^*_k\|_4^2 + \|\text{cum}_3^*(J^*_k, \tilde{J}^*_k, J^*_k, \tilde{J}^*_k)\|_4\right)^{1/2}.$$  

Substituting the expansion

$$E^*[J^*_k \tilde{J}^*_k(\omega_k)]^2 = E^*[J^*_k \tilde{J}^*_k(\omega_k)]^2 + \|E^*[J^*_k \tilde{J}^*_k(\omega_k)]^2 + \|E^*[J^*_k \tilde{J}^*_k(\omega_k)]^2 + \|\text{cum}_3^*(J^*_k, \tilde{J}^*_k, J^*_k, \tilde{J}^*_k)\|_4\right)^{1/2}.$$  

Thus by using (A.48) we obtain $\|E^*[J^*_k \tilde{J}^*_k]\|_8 = O(1 + \frac{1}{(pT)^{1/2}})$, and thus (A.40).

The proof of (A.41) immediately follows from (A.48) (using $n = 2$ and $q/2 = 8$).

To prove (A.42), we expand it in terms of covariances and cumulants

$$\text{cov}^*(J^*_k \tilde{J}^*_k, J^*_k \tilde{J}^*_k) = \text{cov}^*(J^*_k \tilde{J}^*_k)\text{cov}^*(J^*_k \tilde{J}^*_k) + \text{cov}^*(J^*_k \tilde{J}^*_k)\text{cov}(J^*_k \tilde{J}^*_k) + \text{cum}_3^*(J^*_k, \tilde{J}^*_k, J^*_k, \tilde{J}^*_k, J^*_k),$$

thus by using (A.48) we obtain (A.42).

To prove (A.43), we expand the sample bootstrap spectral density in terms of DFTs to obtain

$$\text{cum}_3^*(J^*_k \tilde{J}^*_k, J^*_k \tilde{J}^*_k, J^*_k \tilde{J}^*_k, J^*_k) = \frac{1}{T} \sum_l K_h(\omega_k - \omega_l)\text{cum}_3^*(J^*_k \tilde{J}^*_k, J^*_k \tilde{J}^*_k, J^*_k \tilde{J}^*_k, J^*_k).$$ (A.50)

By using indecomposable partitions to partition cumulant $\text{cum}_3^*(J^*_k \tilde{J}^*_k, J^*_k \tilde{J}^*_k, J^*_k \tilde{J}^*_k, J^*_k)$ in terms of cumulants of the DFTs, we observe that the leading term is the product of covariances. This gives

$$\|\text{cum}_3^*(J^*_k \tilde{J}^*_k, J^*_k \tilde{J}^*_k, J^*_k \tilde{J}^*_k, J^*_k)\|_8 = \begin{cases} O\left(\frac{1}{(pT)^{1/2}}\right), & (k_l = l \text{ and } k_l + r = k_j) \text{ etc.} \\ O\left(\frac{1}{(pT)^{1/2}}\right), & k_1 = k_2 \text{ or } k_1 + r = l \text{ or } k_j = l. \\ O\left(\frac{1}{(pT)^{1/2}}\right), & \text{otherwise} \end{cases}$$

75
for \(i, j \in \{1, 2\}\). By substituting the above into (A.50), we get

\[
\|\text{cum}_n^\ast(J_{k_1}^\ast T_{k_1+r}, J_{k_2}^\ast T_{k_2+r}, \tilde{f}_T^\ast(\omega_k))\|_{8/3} = \begin{cases} O\left(\frac{1}{bT^{1/2}r^2} + \frac{1}{(pT^{1/2})^2}\right), & k_1 = k_2 \text{ or } k_1 + r = k_2 \text{ or } k_1 = k_2 + r, \\ O\left(\frac{1}{bT^{1/2}r^2} + \frac{1}{(pT^{1/2})^2}\right), & \text{otherwise}, \end{cases}
\]

which proves (A.43). The proofs of (A.44) and (A.45) are identical to the proof of (A.43), hence we omit the details.

To prove (A.46), in the case that \(k_1 = k_2\), \(k_1 = k_2 + r\) or \(k_2 = k_1 + r\) we use Cauchy-Schwarz inequality to give

\[
\left\| E^\ast(\mathcal{I}_{k_1,r,j_1,j_2}^\ast \mathcal{I}_{k_2,r,j_3,j_4}^\ast \mathcal{I}_{j_1,j_2}^\ast(\omega_k) \mathcal{I}_{j_3,j_4}^\ast(\omega_k)) \right\|_2 \\
\leq \left\| E^\ast(\mathcal{I}_{k_1,r,j_1,j_2}^\ast \mathcal{I}_{k_2,r,j_3,j_4}^\ast(\omega_k)) \right\|_2^{1/2} \left\| E^\ast(\mathcal{I}_{j_1,j_2}^\ast(\omega_k)) \right\|_2 \left\| E^\ast(\mathcal{I}_{j_3,j_4}^\ast(\omega_k)) \right\|_2^{1/4}.
\]

We observe that \(\left\| E^\ast(\mathcal{I}_{k_1,r,j_1,j_2}^\ast \mathcal{I}_{k_2,r,j_3,j_4}^\ast(\omega_k)) \right\|_2 = O(1)\), thus by using (A.39) we get (A.46) when either \(k_1 = k_2\) or \(k_1 = k_2 + r\). This bound is too crude when both \(k_1 \neq k_2\), \(k_1 \neq k_2 + r\) and \(k_2 \neq k_1 + r\). Instead, we decompose the expectation as the product of cumulants and use (A.42)-(A.45) to get (A.46). Finally to prove (A.47), we use the Minkowski inequality to give

\[
\left\| E^\ast(\tilde{f}_T^\ast(\omega_k)) - f(\omega_k) \right\|_8 \\
\leq \int \frac{1}{T} \sum_j K_b(\omega_k - \omega_j) [E^\ast(J_j^\ast T_j^\ast) - \tilde{h}_2(\omega_j)] \right\|_8 + \left\| \frac{1}{T} \sum_j K_b(\omega_k - \omega_j) [\tilde{h}_2(\omega_j) - f(\omega_j)] \right\|_8 + \left\| \frac{1}{T} \sum_j K_b(\omega_k - \omega_j) f(\omega_j) - f(\omega_k) \right\|_8,
\]

where \(\tilde{h}_2\) is defined in (4.9). We now bound the above terms. By using Theorem 4.1 (for \(n = 2\), we have

\[
\left\| \frac{1}{T} \sum_j K_b(\omega_k - \omega_j) [E^\ast(J_j^\ast T_j^\ast) - \tilde{h}_2(\omega_j)] \right\|_8 \\
\leq \frac{1}{T} \sum_j K_b(\omega_k - \omega_j) \left\| E^\ast(J_j^\ast T_j^\ast) - \tilde{h}_2(\omega_j) \right\|_8 = O\left(\frac{1}{(pT^{1/2})^2}\right). \]

By using Lemma 4.2(ii), we obtain

\[
\left\| \frac{1}{T} \sum j K_b(\omega_k - \omega_j) [\tilde{h}_2(\omega_j) - f(\omega_j)] \right\|_8 \leq \frac{1}{T} \sum j K_b(\omega_k - \omega_j) \left\| \tilde{h}_2(\omega_j) - f(\omega_j) \right\|_8 = O\left(\frac{1}{T} + \frac{1}{pT^{1/2}} + p\right).
\]

By using similar methods to those used to prove Lemma A.2(i), we have

\[
\frac{1}{T} \sum j K_b(\omega_k - \omega_j) f(\omega_j) - f(\omega_k) = O(b).
\]

Substituting the three bounds above into (A.51) gives (A.47).

Analogous to \(\hat{C}_{T}(r, \ell)\), direct analysis of the variance of \(\hat{C}_{T}^\ast(r, \ell)\) and \(\hat{C}_{T}^\ast(r, \ell)\) with respect to the bootstrap measure is extremely difficult because of the \(\hat{L}^\ast(\omega_k)\) and \(\hat{L}(\omega_k)\) in the definition of \(\hat{C}_{T}^\ast(r, \ell)\) and \(\hat{C}_{T}^\ast(r, \ell)\). However, analysis of \(\hat{C}_{T}^\ast(r, \ell)\) is much easier, therefore to show that the bootstrap variance
converges to the true variance we will show that var\(^*\)(\(\hat{C}_T^s(r, \ell)\)) and var\(^*\)(\(\tilde{C}_T^s(r, \ell)\)) can be replaced with var\(^*\)(\(\hat{C}_T(r, \ell)\)). To prove this result, we require the following definitions

\[
\hat{c}_{j_1,j_2}^s(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} \sum_{s_1,s_2=1}^{d} A_{j_1,s_1,j_2,s_2} \left( \hat{f}_{k,r}^s \right) J_{k,s_1}^s J_{k+r,s_2}^s \exp(i k \omega_k),
\]

\[
\tilde{c}_{j_1,j_2}^s(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} \sum_{s_1,s_2=1}^{d} A_{j_1,s_1,j_2,s_2} \left( E^s(\hat{f}_{k,r}) \right) J_{k,s_1}^s J_{k+r,s_2}^s \exp(i k \omega_k),
\]

\[
\hat{c}_{j_1,j_2}^s(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} \sum_{s_1,s_2=1}^{d} A_{j_1,s_1,j_2,s_2} \left( \hat{f}_{k,r}^s \right) J_{k,s_1}^s J_{k+r,s_2}^s \exp(i k \omega_k),
\]

\[
\tilde{c}_{j_1,j_2}^s(r, \ell) = \frac{1}{T} \sum_{k=1}^{T} \sum_{s_1,s_2=1}^{d} A_{j_1,s_1,j_2,s_2} \left( \hat{f}_{k,r}^s \right) J_{k,s_1}^s J_{k+r,s_2}^s \exp(i k \omega_k).
\]

We also require the following lemma which is analogous to Lemma A.2, but applied to the bootstrap spectral density estimator \(\hat{f}_T^s(\omega)\).

**Lemma A.15** Suppose that \{"\(X_t\)\} is an \(\alpha\)-mixing second order stationary or locally stationary time series (which satisfies Assumption 3.2(L2)) with \(\alpha > 4\) and the moment \(\sup_t ||X_t||_s < \infty\) where \(s > 4\alpha/(\alpha - 2)\). For \(h \neq 0\) either the covariance of locally stationary covariance satisfies \(|\kappa(h)|_1 \leq C|h|^{-(2+\varepsilon)}\) or \(|\kappa(\nu; h)|_1 \leq C|h|^{-(2+\varepsilon)}\) for some \(\varepsilon > 0\). Let \(J_T^s(\omega_k)\) be defined as in Step 5 of the bootstrap scheme.

(a) If \(Tp^2 \to \infty\) and \(p \to 0\) as \(T \to \infty\), then we have

\[
(i) \sup_{1 \leq k \leq T} |E^s[\hat{f}_T^s(\omega_k)] - f(\omega_k)| = O\left( \frac{1}{pT} + \frac{1}{T^{3/2}} + \frac{1}{T^{2p^2}} \right)\]

\[
(ii) \sup_{1 \leq k \leq T} |E^s[\hat{f}_T^s(\omega_k)] - f(\omega_k)|_1 \xrightarrow{P} 0,
\]

(iii) Further, if \(f(\omega)\) is nonsingular on \([0, 2\pi]\), then for all \(1 \leq s_1, s_2 \leq d\), we have

\[
\sup_{1 \leq k \leq T} |L_{s_1,s_2}(E^s[\hat{f}_T^s(\omega_k)]) - L_{s_1,s_2}(f(\omega_k))| \xrightarrow{P} 0.
\]

(b) In addition, suppose for the mixing rate \(\alpha > 16\) there exists an \(s > 16\alpha/(\alpha - 2)\) such that \(\sup_t ||X_t||_s < \infty\). Then, we have

\[
||E^s[\hat{f}_T^s(\omega_k)] - f(\omega_k)||_8 = O\left( \frac{1}{pT^{1/2}} + \frac{1}{T^{3/2}} + p + b + \frac{1}{bT} \right).
\]

**PROOF.** To reduce notation, we prove the result in the univariate case. By using Theorem 4.1 and equation (4.14), we have

\[
E^s[J_T^s(\omega_j)]^2 = \hat{h}_2(\omega_j) + R_1(\omega_j),
\]

\[
77
\]
where $\tilde{h}_2(\omega_j)$ is defined in (4.9) and $\|\sup_{1 \leq j \leq T} |R_1(\omega_j)|\|_2 = O(\frac{1}{T^{1/2}})$. From $E^*(\tilde{f}_T^*(\omega_k)) = E^*(\frac{1}{T} \sum_j K_0(\omega_k - \omega_j)|J_T^*(\omega_j)|^2)$ and the result above, we get

$$E^*(\tilde{f}_T^*(\omega_k)) = \tilde{f}_T(\omega_k) + R_2(\omega_k),$$ (A.54)

where $\tilde{f}_T(\omega) = \frac{1}{T} \sum_{|r| < T-1} \lambda_\omega(r)(1 - |r|)\exp(-ir\omega/2)\tilde{h}_2(r)$ and $\tilde{h}_2(r)$ is defined in (4.2). It can be shown that $\|\sup_{\omega_k} R_2(\omega_k)\|_2 = O(\frac{1}{T^{1/2}})$. Since $R_2(\omega_k)$ is negligible, for the rest of the proof, we only need to analyze the leading term $\tilde{f}_T(\omega)$ (note that unlike $E^*(\tilde{f}_T^*(\omega_k))$, $\tilde{f}_T(\omega)$ is defined over $[0, 2\pi]$ and not just for the fundamental frequencies).

Using the same methods as those used in the proof of Lemma A.2(a), it is straightforward to show that

$$E[\tilde{f}_T(\omega)] = f(\omega) + R_3(\omega),$$ (A.55)

where $\sup_{\omega} |R_3(\omega)| = O(\frac{1}{T^{1/2}} + b + p)$. This proves $\sup_{1 \leq k \leq T} |E^*[\tilde{f}_T^*(\omega_k)]| - f(\omega_k)| = O(p + b + (bT)^{-1} + (p^2T)^{-1})$. Using (4.6), it is straightforward to show that $\var(\tilde{f}_T(\omega)) = O(1/(pT))$, therefore by (A.54) and the above we have shown (ai).

By using identical methods to those used to prove Lemma A.2(ci) we can show $\sup_{\omega} |\tilde{f}_T(\omega) - E[\tilde{f}_T(\omega)]| \overset{p}{\to} 0$. Thus from uniform convergence of $\tilde{f}_T(\omega)$ and part (ai) of this lemma we immediately obtain uniform convergence of $E^*[\tilde{f}_T^*(\omega_k)]$ ($\sup_{1 \leq k \leq T} E^*[\tilde{f}_T^*(\omega_k)] - f(\omega_k))$. Similarly to show (aiii) we apply identical methods to those used in the proof of Lemma A.2(cii) to $\tilde{f}_T(\omega)$.

Finally, to show (b), we use that

$$\|E^*[\tilde{f}_T^*(\omega_k)] - f(\omega_k)\|_8 \leq \|\tilde{f}_T(\omega_k) - E[\tilde{f}_T(\omega_k)]\|_8 + |E[\tilde{f}_T(\omega_k)] - f(\omega_k)| + \|R_2(\omega_k)\|_8.$$ 

By using (4.6) and the Minkowski inequality, we can show $\|\tilde{f}_T(\omega_k) - E[\tilde{f}_T(\omega_k)]\|_8 = O((T p^2)^{-1/2})$, where this and the bounds above give (b).

**Lemma A.16** Suppose that Assumption 5.2 and the conditions in Lemma A.15 hold. Let $\tilde{c}_{j_1,j_2}(r, \ell)$ and $\tilde{c}_{j_1,j_2}^*(r, \ell)$ be defined as in (A.52). Then we have

$$T \left( E^*[\tilde{c}_{j_1,j_2}(r_1, \ell_1)] E^*[\tilde{c}_{j_3,j_4}(r_2, \ell_2)] - E^*[\tilde{c}_{j_1,j_2}(r_1, \ell_1)] E^*[\tilde{c}_{j_3,j_4}^*(r_2, \ell_2)] \right) = O_p(a(T, b, p))$$

(A.56)

$$T \left( E^*[\tilde{c}_{j_1,j_2}^*(r_1, \ell_1)] \tilde{c}_{j_3,j_4}^*(r_2, \ell_2) - E^*[\tilde{c}_{j_1,j_2}^*(r_1, \ell_1)] \tilde{c}_{j_3,j_4}^*(r_2, \ell_2) \right) = O_p(a(T, b, p))$$

(A.57)

where $a(T, b, p) = \frac{1}{bT^p} + \frac{1}{bT} + b + \frac{1}{pT^{1/2}} + \frac{1}{pT^{1/2}}$.

**PROOF.** To simplify notation, we prove the result for the case $d = 1$, $\ell_1 = \ell_2 = 0$ and $r_1 = -r_2 = r$ (the proof is identical for $d > 1$, $\ell_1 = \ell_2 \neq 0$ and $r_1 \neq -r_2$). We first prove (A.56). Recalling that the only
where the terms \( \hat{E}(\hat{f}_{k,r}^*) \) is replaced with \( A(E^*(\hat{f}_{k,r}^*)) \), the difference between their expectations squared (with respect to the stationary bootstrap measure) is

\[
T\left( \left[ E^*(\hat{c}^*(r,0)) \right]^2 - \left[ E^*(\hat{e}^*(r,0)) \right]^2 \right) = \frac{1}{T} \sum_{k_1,k_2} \left( E^*[A(\hat{f}_{k_1,r}^*)J_{k_1}^*J_{k_2}^*] + A(E^*(\hat{f}_{k_1,r}^*))A(E^*(\hat{f}_{k_2,r}^*))E^*(J_{k_1}^*J_{k_2}^*) \right)
\]

\[
= \frac{1}{T} \sum_{k_1,k_2} \left( E^*[a_{k_1}^*I_{k_1}^*E^*[a_{k_2}^*I_{k_2}^*] - \hat{a}_{k_1}\hat{a}_{k_2}E^*[I_{k_1,r}E^*[I_{k_2,r}^*]] \right),
\]

(A.58)

where

\[
a_k^* = A(\hat{f}_{k,r}^*), \quad \hat{a}_k = A(E^*(\hat{f}_{k,r}^*)^2) \quad \text{and} \quad \hat{f}_{k,r}^* = \hat{f}_{k,r} - E^*(\hat{f}_{k,r}^*),
\]

(A.59)

and \( I_{k,r} \) is defined in Lemma A.14. To bound the above, we use the Taylor expansion

\[
A(\hat{f}_{k,r}^*) = A(E^*(\hat{f}_{k,r}^*)) + (\hat{f}_{k,r} - E^*(\hat{f}_{k,r}^*))' \nabla A(E^*(\hat{f}_{k,r}^*)) + \frac{1}{2} (\hat{f}_{k,r} - E^*(\hat{f}_{k,r}^*))' \nabla^2 A(E^*(\hat{f}_{k,r}^*)) (\hat{f}_{k,r} - E^*(\hat{f}_{k,r}^*)),
\]

where \( \nabla \) and \( \nabla^2 \) denotes the first and second partial derivative with respect to \( f_{k,r} \) and \( \hat{f}_{k,r}^* \) lies between \( \hat{f}_{k,r} \) and \( E^*(\hat{f}_{k,r}^*) \). To reduce cumbersome notation (and with a slight loss of accuracy, since it will not affect the calculation) we shall ignore that \( \hat{f}_{k,r} \) is a vector and use (A.59) to rewrite the above Taylor expansion as

\[
a_k^* = \hat{a}_k + \int_k \frac{\partial \hat{a}_k}{\partial f} + \int_k^2 \frac{\partial^2 \hat{a}_k}{\partial f^2},
\]

(A.60)

where \( \hat{a}_k^n = \nabla^2 A(\hat{f}_{k,r}^*) \). Substituting (A.60) into (A.58), we obtain the decomposition

\[
T(\left[ E^*(\hat{c}^*(r,0)) \right]^2 - \left[ E^*(\hat{e}^*(r,0)) \right]^2) = \sum_{i=1}^{8} I_i,
\]

where the terms \( \{I_i\}_{i=1}^{8} \) are

\[
I_1 = \frac{1}{T} \sum_{k_1,k_2} \hat{a}_{k_1} \frac{\partial \hat{a}_{k_2}}{\partial f} E^*[I_{k_1,r}^*E^*[I_{k_2,r}^*]],
\]

(A.61)

\[
I_2 = \frac{1}{T} \sum_{k_1,k_2} \frac{\partial \hat{a}_{k_1}}{\partial f} \frac{\partial \hat{a}_{k_2}}{\partial f} E^*[I_{k_1,r}^*E^*[I_{k_2,r}^*]],
\]

\[
I_3 = \frac{1}{T} \sum_{k_1,k_2} \hat{a}_{k_2} E^*[I_{k_1,r}^*\hat{f}_{k_1}^* \frac{\partial^2 \hat{a}_{k_1}}{\partial f^2}] E^*[I_{k_2,r}^*],
\]

\[
I_7 = \frac{1}{T} \sum_{k_1,k_2} \frac{\partial \hat{a}_{k_1}}{\partial f} E^*[I_{k_1,r}^*\hat{f}_{k_1}^* \frac{\partial^2 \hat{a}_{k_1}}{\partial f^2}] E^*[I_{k_2,r}^*],
\]

\[
I_8 = \frac{1}{T} \sum_{k_1,k_2} E^*[I_{k_1,r}^*\hat{f}_{k_1}^* \frac{\partial^2 \hat{a}_{k_1}}{\partial f^2}] E^*[I_{k_2,r}^*\hat{f}_{k_2}^* \frac{\partial^2 \hat{a}_{k_2}}{\partial f^2}] i
\]

79
(with \( \tilde{I}_{k,r}^* = I_{k,r}^* - E^*(I_{k,r}^*) \)) and \( I_4, I_5, I_6 \) are defined similarly. We first bound \( I_1 \). Writing the bootstrap spectral density function estimator as \( \tilde{f}_k^* = \frac{1}{T} \sum_{j} K_b(\omega_k - \omega_j) \tilde{I}_{j,0}^* \) gives

\[
I_1 = \frac{1}{T} \sum_{k_1, k_2, j} \frac{\partial \tilde{a}_{k_1}}{\partial f} E^*(I_{k_1, r}^*) \text{cov}^*(\tilde{I}_{k_2, r}, \tilde{I}_{j,0}^*).
\]

By using the uniform convergence result in Lemma A.15(a), we have \( \sup_k |\tilde{a}_k - a_k| \xrightarrow{p} 0 \). Therefore, \( |I_1| = O_p(1) \hat{I}_1 \), where

\[
\hat{I}_1 = \frac{1}{T} \sum_{k_1, k_2, j} |k_b(\omega_{k_2} - \omega_j)| \cdot |a_{k_1} \frac{\partial \tilde{a}_{k_2}}{\partial f} | \cdot |E^*(I_{k_1, r}^*)| \text{cov}^*(\tilde{I}_{k_2, r}, \tilde{I}_{j,0}^*)|
\]

with \( a_k = A(\tilde{f}_k^*, r) \) and \( \frac{\partial a_k}{\partial f} = \nabla_f A(\tilde{f}_k^*, r) \). Using Cauchy-Schwarz inequality gives

\[
||\hat{I}_1|| \leq \frac{1}{T} \sum_{k_1, k_2, j} |k_b(\omega_{k_2} - \omega_j)| \cdot |a_{k_1} \frac{\partial \tilde{a}_{k_2}}{\partial f} | \cdot ||E^*(I_{k_1, r}^*)||_2 ||\text{cov}^*(\tilde{I}_{k_2, r}, \tilde{I}_{j,0}^*)||_2.
\]

thus we have \( \hat{I}_1 = O_p(\frac{1}{T}) \) and \( I_1 = O_p(\frac{1}{T}) \). We now bound \( I_2 \). By using an identical method to that given above (and the same notation), we have \( |I_2| = O_p(1) \hat{I}_2 \), where

\[
\hat{I}_2 = \frac{1}{T} \sum_{k_1, k_2, j_1, j_2} |k_b(\omega_{k_1} - \omega_{j_1})| \cdot |k_b(\omega_{k_2} - \omega_{j_2})| \cdot \frac{\partial \tilde{a}_{k_1}}{\partial f} \frac{\partial \tilde{a}_{k_2}}{\partial f} \cdot ||\text{cov}^*(\tilde{I}_{k_1, r}, \tilde{I}_{j_1,0})\text{cov}^*(\tilde{I}_{k_2, r}, \tilde{I}_{j_2,0})||_2
\]

which gives \( \hat{I}_2 = O_p(\frac{1}{T}) \), and thus \( I_2 = O_p(\frac{1}{T}) \).

To bound \( I_3 \), we use Hölder’s inequality to give

\[
|I_3| \leq \frac{1}{2} T \sum_{k_1, k_2} |\tilde{a}_{k_2}| \left( E^* \left| \tilde{f}_{k_1}^* \right|^4 \right)^{1/2} \left( E^* |I_{k_1, r}^*|^6 \right)^{1/6} \left( E^* \left| \frac{\partial^2 \hat{a}_{k_1}}{\partial f^2} \right|^3 \right)^{1/3} |E^*(I_{k_2, r})|.
\]

Under Assumption 5.2(B1), we have that \( (E^* \left| \frac{\partial^2 \hat{a}_{k_1}}{\partial f^2} \right|^3)^{1/3} \) is uniformly bounded in probability. Therefore, using this and Lemma A.15(a), we have \( |I_3| = O_p(1) \hat{I}_3 \), where

\[
\hat{I}_3 = \frac{1}{T} \sum_{k_1, k_2} |\tilde{a}_{k_2}| \left( E^* \left| \tilde{f}_{k_1}^* \right|^4 \right)^{1/2} \left( E^* |I_{k_1, r}^*|^6 \right)^{1/6} |E^*(I_{k_2, r})|.
\]

Taking expectations of the above and using Hölder’s inequality gives

\[
E(\hat{I}_3) \leq \frac{1}{T} \sum_{k_1, k_2} |\tilde{a}_{k_2}| \cdot \left( E^* \left| \tilde{f}_{k_1}^* \right|^4 \right)^{1/2} \cdot \left( E^* |I_{k_1, r}^*|^6 \right)^{1/6} \cdot \left( E^* |I_{k_2, r}^*| \right)^{1/3}.
\]

80
Thus by using Lemma A.14, we obtain $|I_3| = O_p(\frac{1}{dTp})$. Using a similar method, we obtain $|I_7| = O_p(1)^\hat{I}_7$, where

$$
\hat{I}_7 = \frac{1}{T} \sum_{k_1,k_2} \left| \frac{\partial a_k}{\partial f} \right| \left( (E^*|I_{k_1,r}^*|^6)^{1/6} \left( E^*|\tilde{f}_{k_1}^*|^4 \right)^{1/2} \right) \left| E^*[\tilde{I}_{k_2,r}^*|\tilde{I}_{k_2}^*] \right| \quad \text{and} 
$$

$$
\|\hat{I}_7\|_1 \leq \frac{1}{T} \sum_{k_1,k_2} \left( (E^*|I_{k_1,r}^*|^6)^{1/6} \left( E^*|\tilde{f}_{k_1}^*|^4 \right)^{1/2} \right) \left( \text{cov}^*[\tilde{I}_{k_2,r}^*,\tilde{I}_{k_2}^*] \right)_\| = O \left( \frac{1}{T^{p^7T^{5/2}}} + \frac{1}{b^2T^{5/2}p^3} \right).
$$

Finally we use identical arguments as above to show that $|I_8| = O_p(1)^\hat{I}_8$, where

$$
\hat{I}_8 \leq \frac{1}{4T} \sum_{k_1,k_2} \left( (E^*|\tilde{f}_{k_1}^*|^4)^{1/2} \left( E^*|I_{k_1,r}^*|^6 \right)^{1/6} \left( E^*|\tilde{f}_{k_2}^*|^4 \right)^{1/2} \left( E^*|I_{k_2,r}^*|^6 \right)^{1/6} \right).
$$

Thus, using similar arguments as those used to bound $\|\hat{I}_3\|_1$, we have $|I_8| = O_p((b^2T)^{-1})$. Similar arguments can be used to obtain the same bounds for $I_1, \ldots, I_6$, which altogether gives (A.56).

To bound (A.57), we write $I_{k,r}^*$ as $I_{k,r}^* = \hat{I}_{k,r}^* + E^*(I_{k,r})$ and substitute this in the difference to give

$$
T(E^*[\hat{c}^*(r,0)]^2 - E^*[\hat{c}^*(r,0)]^2) = \frac{1}{T} \sum_{k_1,k_2} \left( E^* [a_{k_1} a_{k_2} I_{k_1,r}^* I_{k_2,r}^*] - \hat{a}_{k_1} \hat{a}_{k_2} E^*[\hat{I}_{k_1,r}^*,\hat{I}_{k_2,r}^*] \right)
$$

$$
= \frac{1}{T} \sum_{k_1,k_2} E^* \left[ [a_{k_1} a_{k_2} - \hat{a}_{k_1} \hat{a}_{k_2}] \left[ \hat{I}_{k_1,r}^* E^*(I_{k_2,r}^*) + E^*(I_{k_1,r}^*) \hat{I}_{k_2,r}^* + E^*(I_{k_1,r}^*) E^*(I_{k_2,r}^*) \right] \right]
$$

$$
+ \frac{1}{T} \sum_{k_1,k_2} E^* \left[ [a_{k_1} a_{k_2} - \hat{a}_{k_1} \hat{a}_{k_2}] \left[ \hat{I}_{k_1,r}^* \hat{I}_{k_2,r}^* \right] \right].
$$

We now substitute the Taylor expansion of $a_k^*$ about $\hat{a}_k$ in (A.60) into the above to give

$$
T(E^*[\hat{c}^*(r,0)]^2 - E^*[\hat{c}^*(r,0)]^2) = \sum_{i=0}^{8} II_i,
$$

(A.62)

where

$$
II_0 = \frac{1}{T} \sum_{k_1,k_2} E^* \left[ \hat{I}_{k_1,r}^* E^*(I_{k_2,r}^*) + E^*(I_{k_1,r}^*) \hat{I}_{k_2,r}^* + E^*(I_{k_1,r}^*) E^*(I_{k_2,r}^*) \right] \times
$$

$$
\left[ \hat{a}_{k_1} + \hat{f}_{k_1} \frac{\partial \hat{a}_{k_1}}{\partial f} + \hat{f}_{k_1}^2 \frac{1}{2} \left( \frac{\partial^2 \hat{a}_{k_1}}{\partial f^2} \right) \right] \left[ \hat{a}_{k_2} + \hat{f}_{k_2} \frac{\partial \hat{a}_{k_2}}{\partial f} + \hat{f}_{k_2}^2 \frac{1}{2} \left( \frac{\partial^2 \hat{a}_{k_2}}{\partial f^2} \right) \right].
$$
II_1 = \frac{1}{T} \sum_{k_1, k_2} \tilde{a}_{k_1} \frac{\partial \tilde{a}_{k_2}}{\partial f} E^* (\tilde{I}_{k_1, r} \tilde{I}_{k_2, r} \tilde{I}_{\tilde{k}_2}),

II_2 = \frac{1}{T} \sum_{k_1, k_2} \frac{\partial \tilde{a}_{k_1}}{\partial f} \frac{\partial \tilde{a}_{k_2}}{\partial f} E^* [\tilde{I}_{k_1, r} \tilde{I}_{k_1, r} \tilde{I}_{k_2, r} \tilde{I}_{\tilde{k}_2}],

II_3 = \frac{1}{2T} \sum_{k_1, k_2} \tilde{a}_{k_1} E^* \left[ \tilde{I}_{k_1, r} \tilde{I}_{k_1, r} \frac{\partial^2 \tilde{a}_{k_1}}{\partial f^2} \tilde{I}_{k_2, r} \tilde{I}_{\tilde{k}_2} \right],

II_7 = \frac{1}{T} \sum_{k_1, k_2} \frac{\partial \tilde{a}_{k_2}}{\partial f} E^* \left[ \tilde{I}_{k_1, r} \tilde{I}_{k_1, r} \frac{\partial^2 \tilde{a}_{k_1}}{\partial f^2} \tilde{I}_{k_2, r} \tilde{I}_{\tilde{k}_2} \right],

II_8 = \frac{1}{4T} \sum_{k_1, k_2, r, \ell} E^* \left[ \tilde{I}_{k_1, r} \tilde{I}_{k_1, r} \frac{\partial^2 \tilde{a}_{k_1}}{\partial f^2} \tilde{I}_{k_2, r} \tilde{I}_{k_2, r} \tilde{I}_{\tilde{k}_2} \right],

and II_4, II_5, II_6 are defined similarly. By using similar methods to those used to bound (A.56), Assumption 5.2(B1), (A.39), (A.40) and (A.41), we can show that \(|II_0| = O_p((T p^2 b)^{-1})\). To bound \(|II_1|, \ldots, |II_8|\) we use the same methods as those used to bound (A.56) and the bound in (A.39), (A.40), (A.43), (A.44), (A.45) and (A.46) to show (A.57), we omit the details as they are identical to the proof of (A.56).

\[\square\]

**Lemma A.17**

Suppose that Assumption 5.2(B2) and the conditions in Lemma A.15 hold. Let \( \bar{c}_1^{\ast, j_2}(r, \ell) \), \( \bar{c}_2^{\ast, j_2}(r, \ell) \) and \( \bar{c}_1^{j_2, j_2}(r, \ell) \) be defined as in (A.52). Then, we have

\[
T \left( E^* [\bar{c}_1^{j_2, j_2}(r, \ell)] E^* [\bar{c}_2^{j_2, j_4}(r_2, \ell_2)] - E^* [\bar{c}_1^{j_2, j_2}(r, \ell)] E^* [\bar{c}_2^{j_2, j_4}(r_2, \ell_2)] \right) = O_p (a(T, b, p)),
\]

\[\text{(A.63)}\]

\[
T \left( E^* [\bar{c}_1^{j_2, j_2}(r, \ell)] E^* [\bar{c}_2^{j_2, j_4}(r_2, \ell_2)] - E^* [\bar{c}_1^{j_2, j_2}(r, \ell)] E^* [\bar{c}_2^{j_2, j_4}(r_2, \ell_2)] \right) = O_p (a(T, b, p)),
\]

\[\text{(A.64)}\]

\[
T \left( E^* [\bar{c}_1^{j_2, j_2}(r, \ell)] E^* [\bar{c}_2^{j_2, j_4}(r_2, \ell_2)] - E^* [\bar{c}_1^{j_2, j_2}(r, \ell)] E^* [\bar{c}_2^{j_2, j_4}(r_2, \ell_2)] \right) = O_p (a(T, b, p)),
\]

\[\text{(A.65)}\]

\[
T \left( E^* [\bar{c}_1^{j_2, j_2}(r, \ell)] E^* [\bar{c}_2^{j_2, j_4}(r_2, \ell_2)] - E^* [\bar{c}_1^{j_2, j_2}(r, \ell)] E^* [\bar{c}_2^{j_2, j_4}(r_2, \ell_2)] \right) = O_p (a(T, b, p)),
\]

\[\text{(A.66)}\]

where \( a(T, b, p) = \frac{1}{\sqrt{p^2}} + \frac{1}{\sqrt{T}} + \frac{1}{\sqrt{p^2 T}} + b + \frac{1}{\sqrt{p^2 T}} \).

**PROOF.** Without loss of generality, we consider the case \( d = 1, \ell_1 = \ell_2 = 0 \) and \( r_1 = -r_2 = r \) and use the same notation introduced in the proof of Lemma A.16. To bound (A.63), we use the Taylor expansion

\[
\tilde{a}_{k_1} \tilde{a}_{k_2} - a_{k_1} a_{k_2} = \tilde{f}_{k_2} a_{k_1} \frac{\partial a_{k_2}}{\partial f} + \tilde{f}_{k_1} a_{k_2} \frac{\partial a_{k_1}}{\partial f} + \frac{1}{2} \tilde{f}_{k_2} a_{k_1} \frac{\partial^2 a_{k_2}}{\partial f^2} + \frac{1}{2} \tilde{f}_{k_1} a_{k_2} \frac{\partial^2 a_{k_1}}{\partial f^2} + \tilde{f}_{k_1} \tilde{f}_{k_2} \frac{\partial a_{k_2}}{\partial f} \frac{\partial a_{k_1}}{\partial f},
\]

\[\text{(A.67)}\]

where \( a_k = A(\tilde{f}_{k, r}) \), \( \tilde{a}_k = A(\tilde{f}_{k, r}) \) and \( \tilde{f}_{k, r} \) lies between \( \tilde{f}_{k, r} \) and \( \tilde{f}_{k, r} \). Using the above we have

\[
T \left( (E^* [\bar{c}^\ast (r, 0)] - (E^* [\bar{c}^\ast (r, 0)])^2 \right) = \sum_{i=1}^3 III_i,
\]

\[\text{(A.68)}\]
where

\[
III_1 = \frac{2}{T} \sum_{k_1, k_2} a_{k_1} \frac{\partial a_{k_2}}{\partial f} \tilde{f}_{k_2} E^\ast(I_{k_1, r})E^\ast(I_{k_2, r}),
\]

\[
III_2 = \frac{1}{T} \sum_{k_1, k_2} a_{k_1} \frac{\partial a_{k_2}^2}{\partial f^2} \tilde{f}_{k_2} E^\ast(I_{k_1, r})E^\ast(I_{k_2, r}),
\]

\[
III_3 = \frac{1}{T} \sum_{k_1, k_2} \tilde{f}_{k_1, k_2} \frac{\partial \tilde{a}_{k_1}}{\partial f} \frac{\partial \tilde{a}_{k_2}}{\partial f} E^\ast(I_{k_1, r})E^\ast(I_{k_2, r}).
\]

By using Lemma A.15, (A.40) and (A.53) and the same procedure used to bound (A.56), we obtain (A.63).

To bound (A.64), we use a similar decomposition to (A.68) to give

\[
T \left(E^\ast[\tilde{c}^\ast(r, 0)]^2 - E^\ast[\tilde{c}^\ast(r, 0)]^2\right) = \sum_{i=0}^{3} IV_i,
\]

where

\[
IV_0 = \frac{1}{T} \sum_{k_1, k_2} E^\ast(\tilde{I}_{k_1, r}^\ast E^\ast(I_{k_2, r}) + E^\ast(I_{k_1, r})\tilde{I}_{k_2, r}^\ast + E^\ast(I_{k_1, r})E^\ast(I_{k_2, r})) [\tilde{f}_{k_2} \tilde{a}_{k_1} \frac{\partial \tilde{a}_{k_2}}{\partial f} + \tilde{f}_{k_1} \tilde{a}_{k_2} \frac{\partial \tilde{a}_{k_1}}{\partial f} + \tilde{f}_{k_2} \tilde{a}_{k_1} \frac{\partial \tilde{a}_{k_2}}{\partial f} + \tilde{f}_{k_1} \tilde{a}_{k_2} \frac{\partial \tilde{a}_{k_1}}{\partial f}],
\]

\[
IV_1 = \frac{2}{T} \sum_{k_1, k_2} a_{k_1} \frac{\partial a_{k_2}}{\partial f} \tilde{f}_{k_2} E^\ast(\tilde{I}_{k_1, r}^\ast \tilde{I}_{k_2, r}^\ast),
\]

\[
IV_2 = \frac{1}{T} \sum_{k_1, k_2} a_{k_1} \frac{\partial a_{k_2}^2}{\partial f^2} \tilde{f}_{k_2} E^\ast(\tilde{I}_{k_1, r}^\ast \tilde{I}_{k_2, r}^\ast),
\]

\[
IV_3 = \frac{1}{T} \sum_{k_1, k_2} \tilde{f}_{k_1, k_2} \frac{\partial \tilde{a}_{k_1}}{\partial f} \frac{\partial \tilde{a}_{k_2}}{\partial f} E^\ast(\tilde{I}_{k_1, r}^\ast \tilde{I}_{k_2, r}^\ast).
\]

Again using the same methods to bound (A.56), Lemma A.15 (A.41), (A.44) and (A.53) we obtain \( IV_i = O_p(b + \frac{1}{T_{p'}} + \frac{1}{pT_{1/2}} + \frac{1}{T_{p'}}) \), and thus (A.64).

To bound (A.65) and (A.66) we use identical methods to those given above, hence we omit the details.

\[\square\]

**PROOF of Lemma 5.2** We will prove (ii), the proof of (i) is similar. We observe that

\[
T \left( \text{cov}^\ast[\tilde{c}_{j_1, j_2}^\ast(r, \ell_1), \tilde{c}_{j_3, j_4}^\ast(r, \ell_2)] - \text{cov}^\ast[\tilde{c}_{j_1, j_2}^\ast(r, \ell_1), \tilde{c}_{j_3, j_4}^\ast(r, \ell_2)] \right)
\leq T \left( E^\ast[\tilde{c}_{j_1, j_2}^\ast(r, \ell_1)\tilde{c}_{j_3, j_4}^\ast(r, \ell_2)] - E^\ast[\tilde{c}_{j_1, j_2}^\ast(r, \ell_1)\tilde{c}_{j_3, j_4}^\ast(r, \ell_2)] \right)
+ T \left( E^\ast[\tilde{c}_{j_1, j_2}^\ast(r, \ell_1)] E^\ast[\tilde{c}_{j_3, j_4}^\ast(r, \ell_2)] - E^\ast[\tilde{c}_{j_1, j_2}^\ast(r, \ell_1)] E^\ast[\tilde{c}_{j_3, j_4}^\ast(r, \ell_2)] \right).
\]
Substituting (A.56)-(A.64) into the above gives the bound $O_p(a(T, b, p))$. By using a similar method, we can show

$$T \left( \text{cov}^* \left[ \hat{c}_{j_1, j_2}(r, \ell_1), \hat{c}_{j_3, j_4}(r, \ell_2) \right] - \text{cov}^* \left[ \tilde{c}_{j_1, j_2}(r, \ell_1), \tilde{c}_{j_3, j_4}(r, \ell_2) \right] \right) = O_p(a(T, b, p)).$$

Together, these two results give the bounds in Lemma 5.2. □

**PROOF of Theorem 5.2** The proof of (i) (in the case of fourth order stationarity) follows by using that $\mathbf{W}_n^*$ is a consistent estimator of $\mathbf{W}_n$ (see Theorem 5.1 and Lemma 5.2) therefore

$$|T_{m,n,d}^* - T_{m,n,d}| \xrightarrow{P} 0.$$

Since $T_{m,n,d}^*$ is asymptotically a chi-squared (see Theorem 3.4), it immediately follows from the above that $T_{m,n,d}^*$ is asymptotically a chi-squared too.

To prove (ii), we need to consider the case that $\{X_t\}$ is locally stationary with $A_n(r, \ell) \neq 0$ for some $0 \leq r \leq m$. From Theorem 3.6, we know that $\sqrt{T}(\Re \hat{K}_n(r) - \Re A_n(r) - \Re B_n(r))$ and $\sqrt{T}(\Im \hat{K}_n(r) - \Im A_n(r) - \Im B_n(r))$ have a finite variance and are asymptotically normal with mean asymptotically equal to zero. Therefore, since $\mathbf{W}_n^* = O(p^{-1})$, we have $(\mathbf{W}_n^*)^{-1/2} = O(p^{1/2})$. This altogether gives

$$|\sqrt{T}(\mathbf{W}_n^*)^{-1/2}\Re K_n(r)|^2 + |\sqrt{T}(\mathbf{W}_n^*)^{-1/2}\Im K_n(r)|^2 = O_p(Tp),$$

and thus the required result. □
